Blood lipid determinations were made in 400 patients from 25 to 100 years of age. Roentgenograms of 650 patients were reviewed. An intensive survey was made of 75 patients, aged 80 to 100 years, with no previous histories of diabetes, or of coronary, metabolic, endocrine, or venereal disease. It was found that blood lipids contribute little to diagnosis and prognosis. The total lipids are low in the older group; cholesterol, phospholipids, and the phospholipid/cholesterol ratio are statistically inconclusive. A low lipoprotein atherogenic index may represent a current rate of atherogenesis or previously existing atherogenesis in the older age group. Determination of this index is not of any practical clinical value in the older group. There is furthermore no justification for electrophoretic or ultracentrifuge determinations in elderly patients with atherosclerosis, but the degree of dilatation of the aorta as well as the degree of calcification as seen in the roentgenogram is of extreme importance. Aortic arch calcification is increased in proportion to the degree of widening of the aorta arch. Lateral views of the abdominal aorta should be taken routinely. There is no electrocardiographic pattern typical of the aged person. Ballistocardiography is far from perfect, and the technical errors associated with it are greatly multiplied in old persons. Correlations of eyeground studies with other clinical findings are high. Total lipids, certain serum lipoproteins, the atherogenic index, the degree of aortic calcification, and the degree of aortic dilatation—all increase from youth until the "threshold" age of 60 to 75, after which there is a decline or reversal of trends. No definite conclusions are as yet available with regard to the changes taking place during the "threshold" age.

Duodenal Ulcer as an Occasional Etiologic Factor in Obstructive Jaundice. W. J. Snape. Ann. Int. Med. **42**:1001-1010 (May) 1955 [Lancaster, Pa.].

Despite the close anatomic relationship between the extrahepatic biliary system and the duodenum, jaundice is infrequently reported in patients with duodenal ulcer. In a period of three years, however, Snape observed six patients in whom duodenal ulcer was associated with jaundice. Reflection on the anatomy of the area adjacent to the duodenum suggests that the duodenal ulcer may cause occlusion of the common bile duct (1) by means of impingement of the ulcer or its inflammatory reaction on the biliary papilla—this is an uncommon mode of obstruction; (2) by compression of the common bile duct due to inflammation and edema of the pancreas resulting from a posterior penetrating ulcer since in 75% of the population the common duct travels behind the superior portion of the duodenum and is embedded in the pancreas; and (3) through involvement of the gastrohepatic ligament in deeply penetrating or perforating ulcers. The elevated alkaline phosphatases, the prompt response to vitamin K, the absence of urine urobilinogen, the prompt recession of jaundice with ulcer therapy, and liver biopsy all tend to confirm the presence of obstructive jaundice in these patients with duodenal ulcer. Moreover, surgical exploration confirmed this hypothesis in three of the patients. The author concludes that duodenal ulcer may cause obstructive jaundice in some patients.

Treatment of Pain in Cancer Patients. F. Fabris. Presse méd. **63**:727 (May 14) 1955 (In French) [Paris, France].

Thirty-two patients with neoplasms causing pain were treated with promethazine and chlorpromazine in addition to the analgesics they habitually received. The addition of the two drugs caused a decrease in the amount of analgesics required. Toxic reactions to promethazine and chlorpromazine were minimal. The former drug has a powerful antihistaminic and hypnagogic effect, while the latter produces psychosomatic dissociation with effects comparable to those of lobectomy. The improvement in general well-being was striking in these patients. Tumors that are ulcerated, infected, or threatened (because of irradiation) with localized inflammatory reactions benefit the most from this treatment.

Application of Homeostatic Principles to the Practice of Parenteral Fluid Therapy. N. B. Talbot, G. A. Kerrigan, J. D. Crawford and others. New England J. Med. **252:**856-862 (May 19) and 898-906 (May 26) 1955 [Boston].

In patients undergoing parenteral therapy with fluids, as in those taking food and fluids orally, the body's homeostatic systems may be expected to function satisfactorily only if necessary constituents are provided in reasonably generous and yet physiologically tolerable amounts. This report is concerned with the physiological characteristics and clinical use of dextrose in water; 0.85% sodium chloride in 5% dextrose solution; saline lactate in 5% dextrose solution (a liter of this solution is prepared by mixing 30 ml. of molar sodium lactate, 750 ml of 5% sodium chloride in dextrose, and 220 ml. of 5% dextrose in water); and a potassium-containing multiple electrolyte solution in 5% dextrose. Successful use of the suggested guides to therapy depends on careful appraisal of the status of the particular therapeutic needs of each patient. To permit the application of therapeutic considerations to patients varying in size from the premature infant to the adult, most of the values are expressed in terms of square meter of body surface per unit of time. The approximate surface area of patients of various weights may be estimated with the aid of a table, which lists 0.15 square meters as the surface area equivalent of an infant weighing 4.4 lb. (2,000 gm.) and 2.05 square meters as the surface area equivalent of a person weighing 220 lb. (100 kg.). It is concluded that the application of homeostatic principles should make it possible both to improve and to simplify the practice of parenteal fluid therapy.

Interrelationship of Acute Alkalosis and Potassium Metabolism: A Clinical Study. C. R. Kleeman, M. E. Rubini, E. Lamdin and others. Metabolism 4:238-249 (May) 1955 [New York].

A 35-year-old woman who ingested 200 cc. of an antifreeze compound containing 80% methyl alcohol, with suicidal intent, was given intravenously 1,600 mEq. (about 27 mEq. per kilogram of body weight) of hypertonic sodium bicarbonate (2,700 cc. of a 5% solution) within three hours. Her severe acidosis on admission to the hospital was rapidly converted in a marked metabolic alkalosis associated with the risk of overtreatment but justified because of the grave prognosis of untreated methanol intoxication. Her acute metabolic alkalosis was associated with potassium depletion that potentiated the original metabolic alkalosis. At the height of the potassium depletion her urine became acid despite severe extracellular alkalosis. She vomited four times in the 10th to 20th hours of hospitalization but felt well thereafter. Fluid diet supplemented with parenterally given solutions containing 5% dextrose and potassium was given on the second hospital day, after which a full hospital diet was tolerated. Coincident with potassium repletion there was a further increase in the patient's urinary excretion of ammonia and titratable acid. This sequence of events is consistent with the view that alkalosis secondary to potassium depletion is associated with an intracellular acidosis and that the "paradoxical" aciduria potentiates, but is not the cause of, hypokalemic alkalosis. The continued excretion of ammonia in an alkaline urine associated with extracellular alkalosis emphasizes that factors other than the pH of urine and/or extracellular fluids are important stimuli for ammonia production. The patient was discharged asymptomatic from the hospital on the fifth day.

Safer Pneumoperitoneum Refills. J. B. Devine and E. Dunner. Dis. Chest **27:**553-557 (May) 1955 [Chicago].

The authors show that the physician inducing a pneumoperitoneum should pay attention to the phase of respiration during which the needle is introduced into the abdominal cavity. The height of the abdominal air space in a patient with artificially induced pneumoperitoneum is increased on deep inspir tion as compared with expiration. It is therefore concluded tha for those patients receiving pneumoperitoneum refills in who an appreciable air space is not present, the insertion of th needle at the end of a deep inspiration is safer and reduces th danger of injuring the abdominal viscera.

SURGERY

A Maneuver for Extracting Clots from the Atrium at the Tim of Mitral Commissurotomy: With Reports of Four Consecuti Cases. *W. L. Jamison,* K. V. S. Rao and C. P. Bailey. J. Thorac *Surg. 29:541-551* (May) *1955* [St. Louis].

The usual technique of performing *commissurotomy* is enter the left atrium with the right index finger through incised area in the left auricular appendage *that* has been pre ously enclosed by a purse-string suture. Commissurotomy m be performed either with the guillotine knife or merely by digi pressure. One of the most dreaded complications is that of fin ing a ball thrombus *in* the auricle attached by a *thin* pedicle a *waving freely in the* blood stream. These clots may be 3 to 4 c *in diameter. During* any *manipulation* of the left auricular a pendage, *the left* common carotid artery and the right innomin *artery are clamped. While this technique* has reduced the haza from clots as far as emboli to the brain at the time of operati *are concerned, the* postoperative *threat is still* present *if* the c *is not removed.* The authors describe a maneuver that one *them* (W. L. J.) *used to remove clots successfully* in four co secutive cases during the past six months. This maneuver co prises three steps: (1) compressing the clot between the gloved index finger and auricle; (2) extracting the clot by fin *traction and grasping with a Kelly clamp;* and (3) getting of any loose particles by allowing the unclamped auricle to ble freely during the time between pronation and supination of hand. In the first of the four patients the auricular append was so small that the surgeon was able to insert only the fi finger. Jamison found this a safe and efficient method of deali with a small, thrombosed appendage. If the fifth finger does have sufficient strength to open the valve, a guillotine knife then be used. In the second patient, who had Raynaud's dise in addition to rheumatic fever, an attempt was made to wa out any clots in the atrium by merely opening the Satinsky clan This proved ineffectual in that a large clot was subsequen palpated *in the* left atrium. This *shows the need for* an additio technique to deal with these clots rather than merely bleedi the appendage. In case 3, flushing the appendage by opening *Satinsky* clamp was *sufficiently* effective to enable the opera to get his finger to the valve. All loose clots in the appenda were removed by *this* maneuver. The large *atrial* clot was p pated after a commissurotomy and was *in* the posterior super aspect of the atrium. In case 4, the clot was *small,* and its extr tion was much easier in that the diameter of the index fin was slightly wider than the diameter of the clot, but a clot this size in the cerebral or popliteal artery could easily ca death of the tissue involved.

Resection and Anastomosis of the Bronchus Carried out in **Case of Benign Tumor.** A. *Bikfalvi* and *S. Dubecz. J. Thorac* Surg. **29:**488-496 (May) 1955 [St. Louis].

Bronchoscopy revealed a tumor in the right main bronch of a 42-year-old man. Although a biopsy suggested "oat c carcinoma," the patient's favorable general *condition and* long history interspersed with suppurative *symptoms and hemo* tyses suggested the *possibility* of a bronchial *adenoma, and th* was corroborated by a new bronchoscopic examination and t histological studies of a biopsy specimen. In order to save t middle and lower lobes, the authors decided on a bronchoplast operation. After inducing an artificial pneumothorax, a thoraco omy was performed. In the course of the operation, the upp lobe bronchus was amputated, and through this bronchotom aperture the part of the tumor that occluded the orifice of th upper lobe bronchus could be seen. Then the bronchus was cut transversely, nearly at a level with the carina. The bottom level of the transverse section was 1 cm. above the point of origin of the middle lobe bronchus. To avoid disproportion of the two lumina, the intermediate bronchus was amputated in an oblique direction. Then an end-to-end anastomosis was performed with thin and everted mattress sutures of silk, stitching up the paries membranacea of the bronchus to achieve uniformity of the lumen of the bronchus. The suture line was closed hermetically, and no narrowing of the caliber was observed. The removed section of the bronchus measured about 30 mm. The suture line was covered with mediastinal pleura dissected from the region of the vena azygos. The thorax was then closed and drained by two de Pezzer catheters. By resecting the right main bronchus and the intermediate bronchus and bridging over the resulting break by an end-to-end anastomosis it was possible to preserve the function of the middle and lower lobes, and avoid a mutilating pneumonectomy. Six months later the patient was free from symptoms and had resumed his former occupation. The case proves that a large segment of one of the main bronchi can be removed and an anastomosis can then be made without inserting a prosthesis or a graft. Although other reports indicate that at most 2 cm. can be resected, in this case the resected portion of the bronchus measured 3 cm. An artificial suture line, avoidance of overtautness, an anastomosis free from stenosis, and quick expansion of the lung are important factors in the success of this operation.

The Masked Bronchopleural Fistula. B. J. Franz and J. D. Murphy. J. Thoracic Surg. 29:512-517 (May) 1955 [St. Louis].

The symptoms and signs of postresection bronchopleural fistulas occasionally develop in a manner not suspected until a catastrophe supervenes. Failure to detect such a fistula is likely when surgeons must leave the postoperative care to staff members who are not aware of the dangers that lurk in the "alveolar leak," "space defect," "reluctant reexpansion," or any of the other euphemistic terms that are used to describe this complication. The authors apply the term "masked fistula" to lesions that become evident after a period in which the patient seems to progress satisfactorily. On the basis of statistics from Veterans Administration Hospitals, the authors demonstrate the gradually increasing incidence of segmental resections, as compared to pneumectomies and lobectomies, and they believe that with the increase in segmental resections, the possibility of small alveolar air leaks is augmented. A masked fistula developed following 24 of 625 pulmonary resections, which were performed between 1945 and 1953. The subjective signs most helpful in suspecting a masked fistula are: pain or tightness in the chest, a sensation of blowing air in the pleural cavity, and an increase of red or brown sputum when the patient lies on the side not operated on. Objective signs include: return of fever, roentgenologic evidence of an unabsorbed or increased amount of intrapleural air or the appearance of an air pocket in a new location, unexplained lowering of the intrapleural fluid level, increase in bloody sputum or fluid expectoration after instillation of fibrinolytic agents, expectoration of instilled dyes, smell or taste following instillation of an odor-producing material such as ether into the pleural cavity, bronchoscopic visualization of a fistula, bronchographic demonstration of an abnormal communication between the bronchial tree after injection into a chest wall sinus, subcutaneous emphysema, demonstration of an inexhaustible "air pocket" on thoracentesis, sudden appearance of a pneumothorax after reexpansion of the lung, and failure of the remaining lung to reexpand. A residual pleural space following any form of pulmonary resection could be an occult bronchopleural fistula, and every effort should be made to prove its existence in order to institute treatment and forestall serious complications. Since recognition of these fistulas is often difficult, available tests should be repeated as often as necessary. The initial failure of a test does not mean it will subsequently fail. It is suggested that any patent pleurocutaneous sinus be repeatedly investigated and considered as a possible omen of bronchopleurocutaneous communication.

Traumatic Chylothorax and Thoracic Duct Ligation: Case Report and Review of Literature. J. Goorwitch. J. Thoracic Surg. 29:467-479 (May) 1955 [St. Louis].

A 44-year-old woman had swelling of the face, neck, and upper chest and x-ray evidence of a left hydropneumothorax. Three days earlier she sustained an accidental stab wound to the neck, which drained milky fluid and relatively little blood and which was repaired on the day of the accident. On the basis of aspiration of this milky fluid from the left pleural cavity a diagnosis of chylopneumothorax was made, and this diagnosis was confirmed by the demonstration of fat globules taking up Sudan 3 stain and by ether extraction of fat from the pleural fluid. Although therapy was directed toward support of nutrition and promotion of spontaneous sealing of the chylous fistula, a tendency toward early encapsulation and insufficient drainage became evident. As the patient's general condition began to deteriorate, it was decided that despite the fact that the chylous fistula was cervical rather than intrathoracic and even though the loss of chyle appeared to be diminishing spontaneously, the presence of clotted chylothorax called for operative intervention. Seventeen days after the injury, a left thoracotomy was performed. The left lung was collapsed against the mediastinum. About 3 liters of pink chylous fluid and several handfuls of semiclotted gelatinous material were removed, and decortication of the lung was performed. The "peel," measuring up to 2 mm. in thickness, was thickest over the lower lobe. Reexpansion of the lung was complete. During this portion of the operation chyle could be seen accumulating slowly in the superior portion of the pleural cavity. Following limited mobilization of the esophagus mesial to the aorta, the left vagus nerve and a single thoracic duct were identified. The latter was isolated and ligated with 000 black silk. Ten months after the operation the woman had no symptoms and was doing her regular work. Increasing interest in traumatic chylothorax is due both to the safety and success of intrathoracic ligation of the thoracic duct as well as to the increasing frequency of this lesion as a complication of operations in and about the mediastinum. A total of 17 patients with traumatic chylothorax have been subjected to ligation of the thoracic duct. This was always followed by recovery, and there was no unusual morbidity. By contrast, a mortality of 19% was found among the patients in whom chylothorax was treated by methods other than by ligation of the thoracic duct. Ligation of the thoracic duct is the treatment of choice when after a brief period of management by aspiration or continuous closed drainage the chylous fistula shows no tendency to seal off spontaneously.

Eosinophilic Granuloma of Ribs: Review of Literature and Report of Two Cases with Four and Six and One-Half Year Follow-Up, Respectively. J. F. O'Neill, S. J. Skromak and P. R. Casey. J. Thoracic Surg. 29:528-540 (May) 1955 [St. Louis].

Eosinophilic granuloma of bone, although possibly a form of Letterer-Siwe's and Hand-Schüller-Christian's syndromes, and possibly related to syndromes where bone and skin, or bones and lungs are involved, can occur in one or more sites limited to the skeleton and can run a chronic benign course with complete healing. To date about 189 patients with eosinophilic granulomas of bone have been reported in the literature including the two presented here. Both of the reported patients were entirely well, four and six and one-half years, respectively, after resection of the involved rib segments. The finding of a single eosinophilic granuloma in one bone necessitates a complete skeletal survey and a careful search for involvement of the skin, lymph nodes, bone marrow, lungs, liver, and spleen or any evidence of diabetes insipidus, exophthalmos, or mental retardation. In all patients whose lesions are limited to the skeleton, healing will probably occur, the outlook improving with the age of the patient. In infants and children the prognosis must always be guarded in view of the possible development, months to years later, of Letterer-Siwe's or Hand-Schüller-Christian's syndromes. In adults, the prognosis, although better than in children, should be guarded because of nonhealing, recurrences, new lesions, or involvement of the lungs or skin. Eosinophilic granuloma of bone is diagnosed by biopsy only. Surgical treatment is probably best limited to biopsy or treatment of sequelae. X-ray treatment of lesions may relieve pain and aid in repair. Its use seems indicated until a better method becomes available.

Relapse After Pulmonary Resection During Prolonged Streptomycin-Para-Aminosalicylic Acid Treatment of Pulmonary Tuberculosis: An Analysis of 9 Relapses in 82 Cases. L. H. Capel and R. S. Mitchell. Am. J. Med. *18*:557-560 (April) 1955 [New York].

Of 82 patients with pulmonary tuberculosis who were subjected to pulmonary resection in the course of prolonged treatment, but for less than 12 months, with 1 gm. of streptomycin intramuscularly twice weekly and 12 to 16 gm. of *p*-aminosalicylic acid (PAS) by mouth daily, 11 relapsed at some time after the resection. Two of the 11 patients were seriously ill at the time of the resection and are not considered in the authors' report. Of the other nine, five were receiving combined treatment with streptomycin and PAS for the first time and four were receiving retreatment with these two drugs. Since in each of these nine patients the disease became active again at or near the site of the operation, it is suggested that the surgeon's knife may have been in part responsible for the relapse. This possibility is supported by the occurrence of relapse immediately after the resection and in the course of continued chemotherapy in two patients. Organisms from the tissue of one of these were found to be susceptible to streptomycin and PAS. In a third patient, who had bilateral disease at the outset, worse on the left, all the visible and palpable lesions on the left side were resected. Endobronchial disease was observed microscopically at the margin of the resected specimen. Relapse occurred at the site of operation and not on the opposite side. The total of only three months' chemotherapy doubtless contributed to failure in this case. Potentially dangerous visible and palpable lesions may be removed at the expense of damaging adjacent lung tissue containing invisible and impalpable lesions. This damage may reduce the ability of the lung to hold this remaining disease in check. If living tubercle bacilli are observed in resected tissue, they may also be left behind. Thus inadequate duration of chemotherapy for less than 12 months and the creation of a favorable environment for the growth of tubercle bacilli by operative tissue damage were believed to be related causally to these relapses. The selection of patients for pulmonary resection during prolonged combined treatment with streptomycin and PAS should be based on clinically demonstrated necessity rather than on the immediate safety of the operation. It is necessary to remove the persistently open cavity, which presents great mechanical impediment to healing and from which drug-resistant organisms will probably emerge. When indicated and feasible, resection should be performed early in the course of retreatment with streptomycin and PAS. Patients receiving retreatment with open cavities are in greater danger from resection than are patients with cavities who are treated originally, probably because of the more rapid emergence of drug resistance during retreatment with streptomycin and PAS. The significance of this observation increases as operation is delayed.

Extended Sympathectomy in Arterial Hypertension: I. Immediate Results on the Basis of 122 Interventions. R.-H. Martin and M. Bonamy. Arch. mal. coeur **48**:240-244 (March) 1955 (In French) [Paris, France].

The authors use an expanded Poppen operation that permits the removal both of sympathetic chains containing 10, 11, or even 12 ganglions and of the splanchnic nerves from beginning to end. The kidney is exposed to permit removal of a biopsy specimen, which should be as deep as possible. Histological examination of such specimens has invariably revealed lesions in the glomeruli, tubules, or interstitial tissue. Unilateral adrenalectomy or adrenal medullectomy is now being combined with the ablation of the sympathetic chains. The surgical treatment of hypertension by this method requires from four to six weeks of hospitalization and several months of convalescence; only patients capable of resistance can withstand the serious shock of the procedure. Analysis of the results obtained in 122 patients (225 operations) shows that the 12 immediate postoperative deaths all occurred in the first half of the series when patients were not rigidly selected and several operations were performed in an attempt to save the lives of the patients regardless of their age or the extent of their renal lesions. No deaths occurred among patients who were under 35 years of age. Careful selection, an upper age limit of 40 years, and constant supervision by thoroughly trained personnel during and after the intervention are essential if the operation is to be performed without notable risk to the patient. Observance of these requirements will smooth the postoperative period, which otherwise is apt to be difficult. Early complications usually appear as a pronounced aggravation of one of the clinical symptoms seen during the first days after the operation, e. g., intercostal pain, dyspnea, viscid and sometimes painful expectoration, a febrile syndrome with tachycardia, and dyspnea relieved by transfusions but not by antibiotics. More serious complications, such as pleural effusions, hemiplegia, cerebral edema, and cardiovascular disturbances are rare and usually transient; only three deaths in this series were due to complications of this kind. Severe orthostatic hypotension, which may be due to overextension of the sympathectomy, especially in the lumbar zone, did not appear in these patients. These results show that the decision to operate on young adults with severe hypertension resistant to medical treatment should be based, not on technical considerations, but on the developmental tendencies of the disease, the choice of patients, and the late results of the procedure.

Extended Sympathectomy in Arterial Hypertension: II. Late Results. F. Joly, A. Mathivat, J.-R. Sicot and others. Arch. mal. coeur **48**:245-276 (March) 1955 (In French) [Paris, France].

The effect of extended sympathectomy on patients with arterial hypertension can only be interpreted when the postoperative pressure readings are considered in connection with the changes in the general and functional signs and the visceral lesions. Patients who survive the operation may be divided into (1) those in whom all signs of hypertensive disease regress; (2) those in whom the arterial pressure remains irreducible, but all other hypertensive disturbances disappear; (3) those in whom the operation is without effect; and (4) those in whom improvement is only temporary. Follow-up of 80 patients ranging in age from 18 to 53 showed that 5 died after the first or second stage of the operation; 18 died from one month to 5 years after the operation; and 57 were still alive from two to six years after it. Malignant hypertension, unaffected by the operation, was responsible for 15 of the late deaths. The other three followed complete or partial remissions lasting five years or more. The 19 patients in group 1 and the 17 in group 2 were able to resume normal activity within a few months, or one year at the most, after the operation. All but two of the 17 in group 3 were over 40 years of age and all had severe impairment resulting from their disease. The radiological and electrocardiographic changes, which were particularly frequent in this group, were not influenced by the operation, but retinal changes (hemorrhage with or without papilloretinal edema) disappeared completely in 8 of the 10 patients in whom they were present. Group 4, in which the hypertensive syndrome reappears after a complete remission, is important from the prognostic point of view, because, before the recurrence takes place, everything seems to point to the success of the operation. Some of the patients in group 1, therefore, may later have to be added to the five now listed in group 4. The postoperative findings in this series show that (1) the drop in pressure is often transient in character; (2) the clinical and manometric findings are not always in agreement; and (3) the period of postoperative stabilization of the disease varies with each patient. All attempts to establish precise indications for sympathectomy in patients with hypertension have so far failed, and the results of the operation are so often transitory that it should be reserved for patients in whom other methods of treatment have proved unsuccessful and in whom it is not contraindicated by age or other adverse conditions.

asis Ulcers: An Evaluation of the Effectiveness of Three ethods of Therapy and the Implication of Obliterative Cutaeous Lymphangitis as a Credible Etiologic Factor. C. A. Moyer d H. R. Butcher Jr. Ann. Surg. **141**:577-588 (May) 1955 hiladelphia].

Investigations were undertaken to evaluate the following ethods of treating chronic ulcers of the leg: (1) the injection ligation of varices and the wearing of Unna's boots, elastic ndages, or elastic stockings: (2) the injection or ligation of rices, the wearing of elastic supports, and the grafting of the cer without excision or after its excision, with only a narrow nd 'of surrounding skin; and (3) the ligation, excision, or ipping of varices; the immediate split grafting of the cutaneous fect after the excision of the ulcer and all thickened skin and scia about it; and the wearing of elastic supports thereafter. e third method was best, and the second method was better an the first. The likelihood of failure with the third method is e greater the larger the ulcer, the greater the number of ulcers, e more evident the postoperative edema, and the poorer the ke of graft or the slower the epithelization in small localized imary graft failures. Age, sex, nutritional status, history of tecedent phlebitis, duration and position of the ulcer, the tent of varices, the presence of preoperative edema, and the pe of prior therapy had no apparent relationship to the success failure of the third method of treatment. The use of the ird method whether successful or not did not place life, limb, health in significantly greater jeopardy than they were in fore the treatment was instituted. The authors urge that (1) sorbable ligatures be used for hemostasis; (2) the excision clude the base of the ulcer together with all surrounding elastic skin and thickened fascia; (3) the defect be covered mediately with a split-thickness cutaneous autograft; (4) the et and legs remain on the bed for from 14 to 21 days, since pendency of the leg before the 14th day is attended by lifting the graft from its base by confluent petechial hemorrhages; d (5) elastic supports be worn indefinitely. Whereas the dermal nphatics were found obliterated in the skin adjacent to stasis cers, they were present and initially dilated in the successful in grafts. The superficial lymphatics of the grafts soon established connections with the dermal lymphatics of the skin about em. In areas adjacent to ulcers arising after primary graft take, lymphatics were patent, but to date, no recurrent ulcer has peared in any area of a graft shown to possess lymphatics.

e Management of Bleeding Esophageal Varices Associated th Cirrhosis of the Liver. J. E. Hamilton. Ann. Surg. **141**: 7-647 (May) 1955 [Philadelphia].

The varices associated with cirrhosis of the liver are secondary the increased pressure caused by intrahepatic portal obstruction, but since it is not clear just how this portal obstruction is oduced Hamilton summarizes the chief working hypotheses d the different therapeutic plans arising therefrom, particularly e views on hepatic artery ligation and portal systemic shunts. esophageal bleeding is at an alarming rate or does not spond promptly to bed rest and transfusion, double balloon mponade has become the first line of defense against exsanguiation. In spite of his earlier enthusiasm and the encouraging ports on its use by others it has proved disappointing to the thor, in that bleeding was not controlled in 11 of 20 patients, d 15 of the 20 patients died during the hospitalization in hich double balloon tamponade was tried. He suggests that e results might be improved by more heroic blood replacement d earlier resort to ligation of varices. Of the various procedures at have been tried in the treatment of varices including packing e superior and posterior mediastina with gauze to stimulate colteral circulation, stripping the outer surface of the lower ophagus of its blood supply, plus vagotomy, resection of art or all of the stomach to prevent regurgitation of acid contnts into the esophagus and erosion of varices, hepatic arterial gation, and portal-systemic shunts, the author considers the st the most feasible, but states that arterial ligation has reeived much attention of late. Reviewing the experience of 14 uthors with ligation of the hepatic artery, splenic artery, and ometimes also the left gastric artery, in treating hemorrhage and ascites associated with cirrhosis, he found that among 87 patients 23 died in the hospital and at least 10 more deaths occurred within a year after operation. Bleeding recurred in 60% of the patients. The author therefore questions the safety and efficacy of this procedure. Twenty-nine portacaval shunts and four splenorenal shunts performed on dogs in the laboratory were the background for eight such operations that the author performed on human subjects. If the spleen is large he prefers splenectomy and splenorenal shunt because: (1) the large spleen assures an adequate-sized vein and anastomosis; (2) splenectomy will obviate hypersplenism; and (3) the procedure is slightly the safer of the two. On the other hand, if the spleen is relatively small, a portacaval anastomosis is advisable as it assures a stoma at least 1.5 cm. in diameter. If the portal vein and vena cava are widely separated one must decide between an end-to-side shunt with ligation of the proximal stump of the portal vein or a femoral vein graft between the two veins. One of four patients who were good risks and two of four who were poor risks died. Except for one minor and unverified episode, none of the five who survived bled further. Their general health and liver function, following a temporary decline after operation, returned to a level not significantly better or worse than before the operation.

Indications and Late Results of Ligation of Inferior Vena Cava. J. A. Kirtley Jr., D. H. Riddell and E. C. Hamilton. Ann. Surg. **141**:653-663 (May) 1955 [Philadelphia].

Ligation of the inferior vena cava was performed on seven different indications in 34 patients. Multiple pulmonary emboli was the indication for ligation in 19; other indications were: massive infarction with obscure origin of embolus, ascending thrombosis of the lower extremity above the inguinal ligament with embolus; accidental trauma to the inferior vena cava, septic pelvic thrombophlebitis, embolism in which anticoagulants were contraindicated, and in some patients prophylactic ligation performed during abdominal exploration. The authors regard these indications as valid. Their belief that venous ligation at a level lower than the inferior vena cava is not justified was substantiated. Extraperitoneal operation is regarded as the best technique for ligation of the inferior vena cava. In the postoperative period circular elastic bandages are applied from the base of the toes to the groin bilaterally. The foot of the bed is elevated on 6-in. blocks, and the patient is kept at bed rest for two weeks, being allowed up to void or to sit up for meals only. The authors no longer believe that anticoagulants are essential during the postligation period. Bicycle exercises of the legs are begun during the second week, while the patient is still in bed. Four patients died during the operation. Nine patients have died in all, and one could not be followed. Twenty-two of the remaining 24 patients were capable of normal activity when last seen. Fourteen of the patients have been followed from 25 to 85 months, and the late disabling sequelae (severe edema, ulceration, dermatitis, and pain) were found in only two patients. Those lower extremities with preligation evidence of thrombophlebitis have more serious sequelae than those extremities that were free of disease before ligation. The authors believe that the low incidence of late deleterious effects of vena caval ligation should encourage its use when a true indication for ligation exists.

Use of Reenforcing Metallic Mesh Gauze in Repair of Large Postoperative Ventral Hernias. T. J. Floyd Jr. J. M. A. Georgia 44:225-228 (May) 1955 [Atlanta, Ga.].

The author performed 14 postoperative ventral hernioplasties using tantalum mesh wire as reinforcing suture material. The ages of the patients ranged from 31 to 73 years (average 52). There were 4 men and 10 women. Four had upper abdominal hernias (each following a cholecystectomy, two with a split rectus incision and two with a transverse incision); of the other 10, one had a recurrent inguinal hernia, and nine had subumbilical hernias. Of these nine, three hernias occurred after appendectomies with split rectus incisions, and six after pelvic operations with midline incisions. Of these 14 patients one had a recurrence. There were no deaths in this series. The author believes that the use of this reinforcing material allows of much better results than could be obtained with older methods in the old, weak, obese, poor risk type of patient who is prone to postoperative ventral hernia.

Perforation of the Rectosigmoid Colon Due to Straining. M. P. Birbis. Bordeaux chir., pp. 17-25 (Jan.) 1955 (In French) [Bordeaux, France].

A report is given of four men in whom perforation of the rectosigmoid colon occurred on straining. These patients, whose ages ranged from 38 to 69 years, had suffered from constipation prior to the rupture but had no other complaints referable to the digestive tract. The perforations had a punched-out appearance and were located on the free edge of the sigmoid or rectosigmoid region. In three patients a large, hard stercoroma was found in the pararectal pouch. It would seem that a hernia forming in a weak spot in these chronically constipated patients must be the basic cause of the rupture. Hemorrhage from the rectum, severe abdominal pain, and other signs of peritonitis such as fever follow the rupture. All the patients recovered after surgical closure of the perforation; one died in cachexia resulting from a neoplasm of the larynx, and the others were cured.

Thoughts on Early Diagnosis and Recent Trends in Treatment of Lumbar Pott's Disease in the Adult: With Reference to 82 Cases. S. De Sèze, S. Rampon and C. Guérin. Semaine hôp. Paris 31:1712-1729 (May 20) 1955 (In French) [Paris, France].

The fact that patients with tuberculosis of the vertebrae (Pott's disease) can now be safely operated on under the protection of chemotherapy increases the importance of early diagnosis, because complete removal of the tuberculous focus is possible if the operation is performed while the lesions are still localized. Study of 103 patients with Pott's disease showed that in 82 the condition was localized in the lumbar spine and that the lumbosacral joint was affected oftener than any other part of the spinal column. Most (60%) of these 82 patients were young adults, 31.5% were in the 40 to 60 year age group, and 8.5% were over 60. The diagnostic signs—abscess in the iliac fossa, incipient paraplegia, and psoitis—mentioned in the standard descriptions of Pott's disease were rarely seen; pain, on the other hand, which is usually said not to be present, was in all patients the first symptom noticed. It was found in two principal forms—ordinary backache and referred crural or sciatic pain. The clinical investigation of patients in whom Pott's disease is suspected should consist of (1) an examination of the spine, (2) a neurological examination, (3) a search for abscesses, (4) study of the general signs and of the biological signs of inflammation, and (5) study of the history and a search for other tuberculous foci. The results of this investigation, however, though helpful, are seldom conclusive, because neither the characteristic stiffness of the spine nor any of the other signs suggestive of Pott's disease can be constantly detected. Radiological study, on the contrary, provides a secure basis for the diagnosis by demonstrating the spondylodiskitis that constitutes its fundamental lesion. Some evidence of a change in the intervertebral space is always visible on the standard x-ray films in patients with Pott's disease, but when the reading of the films is complicated by the existence of a congenital malformation or some other condition, tomography may be used to clarify the diagnosis. Puncture biopsy of the vertebral body and direct surgical exploration of the lesion sometimes serve as useful supplementary measures in doubtful cases. Treatment may be either medical or medical and surgical. Chemotherapy usually produces a rapid improvement in the patient's general condition, but since the period of immobilization can be substantially shortened and the quality of the cure improved by removal of the tuberculous focus, the authors advocate the combined method, in which the medical treatment is intended to prepare the patient for the operation and to consolidate his recovery afterwards.

The Problem of the Broken Judet Prosthesis. K. H. Pridi Bone & Joint Surg. 37B:224-227 (May) 1955 [London, Engl

In using the Smith-Petersen cup operation in arthroplast the hip, the author had learned that the blood supply of stump of the femoral neck was the all-important factor in d mining the end-result. When Judet (1950) introduced the ac prosthesis it seemed to the author far sounder to get rid of part of the bone in which the circulation was endangered e by a vascular calamity or by sclerotic changes in the bone i and he decided to try the Judet arthroplasty. The imme results were better. The patients became ambulatory earlier, the range of movement was superior to that after the cup o tion. This improvement was only transient, continuing thr the first and sometimes the second year. At about this stag improvement after the Judet operation appeared to halt, complications began to appear. A falling off of performan a previously satisfactory hip and the gradual reappearanc pain and muscle spasm became evident. The radiograph at period suggested that the prosthesis was loose. Then, on watc these patients for several months, occasionally a typical fra of the prosthesis that resembled an intracapsular fracture o femur would be observed. The author has encountered broken prostheses in a series of about 100 patients. He beli that the acrylic head prosthesis operation should be aband for any patient who intends to lead an active life. The orgin of the operation have discovered that it was not univer satisfactory, and they have changed their prosthesis t oblique-angled femoral head, still made of methyl methacry Eighty per cent of the author's patients are satisfied, an believes that the operation is a good one, but the materi the prosthesis has been found wanting. It must be expected fracture of the prosthesis will occur in about 10%, and as goes on the number might be greater. With regard to the t ment of these patients the author says that in the early st when radiographs show that the stem is eccentric, three m in plaster might allow the prosthesis to gain sufficient fix with fibrous tissue to afford relief, but if this does not help operation should be revised and a more durable type of thesis used. A Küntscher or Watson-Jones nail is not st enough and will break in time. An alternative solution in pat with fractured prosthesis lies in the Girdlestone (1945) o tion, which is final and introduces no new foreign subst that may break and no substance that will wear.

Present Status of Surgical Treatment of Varicose Veins Special Emphasis on Vein Stripping. C. A. Griffith and H. Harkins. West. J. Surg. 63:245-252 (May) 1955 [Seattle, Wa

Surgical vein stripping for the treatment of varicosities introduced before World War I, more or less abandoned betw the two wars, and revived after 1937. Essential to the suc of this therapy is coincident high ligation and thorough divi of the branches of the greater saphenous vein at the regio the fossa ovalis. Most patients with varicose veins severe eno to warrant operation will benefit most from a surgical cedure that may include: (1) high ligation of the saphenous at the fossa ovalis, (2) ligation and division of all branche the saphenofemoral junction, (3) careful inclusion of branches of a bifid saphenous, (4) stripping of the greater sa nous vein from groin to ankle, (5) excision of large vari branches and plexuses, and (6) stripping of the lesser saphen vein. From these six fundamental procedures, a choice can made for individual treatment of the patient with varicose ve

Pseudo-Metastases (Benign Tumors in Patients Previously erated on for a Malignant Neoplasm). A. C. De Vet and H. D. Walder. Arch. chir. neerl. 7:78-84 (No. 1) 1955 (In Engli [Arnhem, Netherlands].

When a neoplasm develops in a patient previously operated for malignant tumor, it is generally assumed that the n growth is a metastasis. Benign tumors may develop in patie who have been operated on for cancer. The authors obser three such patients within two months, which proves that i by no means a rare occurrence. The patients in question h enign tumors of the spinal column. This points up the necessity differentiating between metastases and benign processes of e spinal column. The metastatic nature of a neoplasm should doubted if the patient's general condition is good. In patients ith metastasis in the spinal cord paresis generally precedes nsory disturbances. Metastases in the spinal column or cord arly always give rise to violent pain. Such pain was present two of the reported patients and therefore could not serve a differentiating symptom. Metastases to the spinal cord can nerally be ruled out in the absence of radiological changes. etastases are generally associated with an increased sedimentan rate, and the blood calcium and phosphatase values are also ten increased. These values were normal in the reported tients. The fact that carcinomas of bladder and rectum hardly er give rise to metastases in the spinal column should also be ken into account.

yperparathyroidism. W. F. Suermondt. Arch. chir. neerl. 7:1- (No. 1) 1955 (In English) [Arnhem, Netherlands].

The most important finding in hyperparathyroidism is hyperlcemia, accompanied by hypophosphatemia, hypercalciuria, d hyperphosphaturia. The alkaline phosphatase content of the ood rises as the severity of the osseous changes increases. A w calcium content of the cerebrospinal fluid supports the diagsis. The protein content of the blood and the renal function ould likewise be investigated, because they are important for correct diagnosis. In the presence of severe renal lesions, the lcium content of the blood may be reduced to normal values the result of the retention of phosphates. During the operan all four parathyroids should be exposed, because adenomas y be bilateral; this was the case in 2 of 13 patients in the thor's series. Impairment of the renal function and increase in od pressure make the prognosis more unfavorable. The diagsis should be made early, and treatment should be instituted fore irreversible renal lesions have developed, because the ter will become more severe, even after the hyperparathyroidn has been cured by extirpation of the adenoma.

YNECOLOGY & OBSTETRICS

eatment of Trichomonas, Monilia and Mixed Infections of e Vagina. A. Saucier and R. Simard. Canad. M. A. J. 72:584-5 (April 15) 1955 [Toronto, Canada].

Propi-Vaginal is a vaginal suppository containing sodium opionate, propionic acid, and diiodohydroxyquinoline with ded lactose, dextrose, boric acid, and lactic acid. This agent s used in the treatment of 41 patients with vaginitis due to ichomonas or Monilia organisms or both. A vaginal smear s obtained from each patient, after which a 15-day treatment th three suppositories a day for 3 days and two a day for days was instituted. Then another smear was taken, but atment was continued with one suppository a day for 15 days gardless of smear findings. After this 30-day treatment period other control smear was taken, and finally, 15 days later, a t control examination was made. If the second control smear s still positive, treatment was continued with one suppository ily for 15 days, at the end of which period another smear s taken. This procedure was repeated until a negative result s obtained. Not one case of pain or erythema from the drug curred in this series. Complete cure was obtained in about % of cases. The five patients whose smears remained positive reverted to that state were the most careless in their personal giene.

emophilus Vaginalis Vaginitis: A Newly Defined Specific Infecn Previously Classified "Nonspecific" Vaginitis. H. L. Gardner nd C. D. Dukes. Am. J. Obst. & Gynec. 69:962-976 (May) 1955 t. Louis].

Gardner states that microscopic examination of material from e majority of patients with bacterial vaginitis shows solid elds of small pleomorphic gram-negative bacilli. Vaginal marial had been sporadically submitted to clinical laboratories for culture, but a logical correlation could never be drawn between the culture results and the stained smears, a point that suggested that the organism in the smears was not appearing in the cultures. Dukes studied material from a typical case of bacterial vaginitis. Although microscopic examination showed the characteristic organism in large numbers, no growth was obtained in culture mediums. In material from a second patient a large variety of highly enriched mediums was used, and incubations were made under various oxygen and carbon dioxide tensions. At the end of 48 hours, a 10% sheep blood agar plate, incubated under reduced oxygen tension, was found to contain thousands of minute transparent colonies that could be detected only by reflected light. A smear from these colonies showed bacilli similar to those seen on the direct smear. After finding the identical organism in pure culture in 13 of the next 14 patients considered as having bacterial vaginitis, it appeared that a specific etiological agent had been found to explain the majority of cases of "nonspecific" bacterial vaginitis. The authors assigned the name Hemophilus vaginalis to the newly isolated bacillus. Studies were made on 1,181 female patients. Sexually active women constituted the large majority of the patients but also included were a few children and postmenopausal women. The group included 602 obstetric and 579 gynecologic patients. Microscopic examinations of wet mounts and stained smears were made on patients with symptoms of vaginitis. All patients with an abnormal discharge, considered vaginal in origin, who showed no trichomonads or Monilia by microscopic examination, were subjected to bacteriological studies. Sixty-one of 80 patients with smears positive for trichomonads and 47 of 79 patients with moniliasis were also studied bacteriologically. Studies were also made on control groups. Of the 138 women in whom bacterial vaginitis was detected, 127 (92%) were attributed to Hemophilus vaginalis. The authors present proof of the pathogenicity of this organism and direct attention to the diagnostic character of certain epithelial cells designated "clue cells." H. vaginalis organisms isolated from 41 patients were tested against various antibiotics. The organism was found to be sensitive to bacitracin and to the tetracyclines. The tetracycline group was used for treatment in the early part of the study. When it was found that after treatment with the tetracyclines secondary infections with Monilia, Proteus, or micrococci (staphylococci) were found to be a frequent aftermath, resort was made to intravaginal triple sulfonamide (Ortho) cream. This triple sulfonamide effected cure in 10 of 13 patients. It has the advantage of not encouraging secondary infections. The necessity of the simultaneous treatment of husbands is stressed.

Endometriosis as Sequel of Genital Anomaly. L. Schmidt. Zentralbl. Gynäk. 77:183-187 (No. 5) 1955 (In German) [Leipzig, Germany].

A 16-year-old girl experienced severe cramp-like pains in the right hypogastric region, as well as nausea and vomiting during her menstrual periods. In addition, and during the intermenstrual period, she had drawing pains in the right side of her abdomen. Examination indicated that her uterus was of normal size, but slightly displaced to the left. To the right of the uterus, a mass, the size of an apple, that, however, was not sensitive to pressure was palpated. A tumor of the uterine adnexa, possibly a dermoid cyst, was suspected, but operation revealed instead a duplication of the uterus. Whereas the uterus on the left side was connected with the vagina, that on the right side was closed at the level of the internal uterine os and was connected neither with the vagina nor with the left horn. The left ovary was normal, but the adnexa on the right side were buried in a conglomerate mass and covered by omentum. The right-sided duplicate uterus together with its attachments was removed. Examination of the surgical specimen revealed that the uterine tube had been transformed into a hydrosalpinx. Microscopic examination revealed endometriosis in the basal portions of the myometrium. An extensive endometriosis with old and more recent hemorrhages was found also between tube and omentum. In such a patient it may be difficult to decide whether the endometriosis is a sequel of the anomaly or an accidental concurrence. In the reported case normal menstrual bleeding from duplicate uterus was impossible because of closure, and so it seems plausible that endometriosis was caused by stasis and reflux of the menstrual flow into the abdominal cavity (Sampson's implantation theory). The patient had a normal recovery.

Cesarean Hysterectomy. W. C. Bradbury. West. J. Surg. **63:** 232-244 (May) 1955 [Seattle, Wash.].

A review is made of 22,832 deliveries, of which 1,188 were by cesarean section. Among these, 84 cesarean hysterectomies were performed. There were no maternal deaths. A gradual increase in the percentage of cesarean sections, repeated cesarean sections, and cesarean hysterectomies was noted in the series. Cesarean hysterectomy proved to be a useful, and at times lifesaving, measure. The subtotal procedure is no more difficult to carry out than that done in the nonpregnant patient. Although it accomplishes the immediate need in any case, total cesarean hysterectomy is gradually replacing the subtotal operation. With modern equipment, good anesthesia, good assistance, and adequate training, the entire uterus can safely be removed at the time of cesarean section. Certain technical modifications of the nonpregnant procedure facilitate the total operation and produce better results. Stable patients approaching the menopause can safely be selected for cesarean hysterectomy as a means of sterilization when cesarean section and sterilization are indicated. Cesarean hysterectomy in younger patients should be limited to those with a primary indication for hysterectomy.

Use of Cortisone in the Prevention of Erythroblastosis in Infants of Rh-Sensitized Mothers. I. Dyer, R. C. Smith, J. Dent and others. Am. J. Obst. & Gynec. **69:**1083-1093 (May) 1955 [St. Louis].

Once a mother has produced an infant with the classical effects of Rh sensitivity, the chances are great that in subsequent pregnancies the infants will be equally affected and probably show greater depths of the hemolytic process. No reduction of maternal or infant sensitivity was noted with the use of ethinyl disulfonate or with haptens. Premature termination of pregnancy has not improved the fetal salvage. To the contrary, the prematurity thus induced complicates the management of an already complicated problem. Forty-five Rh-negative isoimmunized pregnant women, 40 of whom had previously produced babies affected by erythroblastosis, were given cortisone in the last trimester of pregnancy in an attempt to improve fetal survival. With meticulous control and selection of patients, the drug was well tolerated by both mother and baby. There was one major reaction in a mother, none in any infant. All reactions were reversible. There were 37 live babies, 8 stillbirths, and 5 neonatal deaths. Five liveborn babies were Rh negative. The over-all fetal mortality rate was 28.8% corrected to 15.5%, if two preventable deaths and four instances of inadequate therapy are deleted. The women studied represent a pregnant population of approximately 15,000. The over-all infant survival correlated with past obstetrical history and duration of drug therapy has not shown sufficient improvement to justify continued use of cortisone in treatment or prevention of erythroblastosis fetalis. The potent weapon in this problem still remains immediate exchange transfusion.

Combined Steroids to Suppress Lactation. P. W. Fiskio. GP **11:** 70-72 (May) 1955 [Kansas City, Mo.].

The authors administered Premarin (water-soluble conjugated equine estrogens) with methyltestosterone to 267 women to produce inhibition of lactation during the puerperium. The decision for suppression came from the patients themselves in 261 instances and was medically recommended in only 6. The dosage was three tablets every four hours for five doses, starting immediately on the patient's return to her room after delivery. Each tablet contained 1.25 mg. of the estrogens and 10 mg. of methyltestosterone. All patients were followed for at least six weeks after delivery. One hundred sixty-six patients (62.4%) who had no breast engorgement or untoward symptoms from the medication were considered to have had excellent results. Those who noticed a full but not painful sensation in the breasts were classified as having mild breast engorgement and were considered to have had good results; this category included 91 patients (33.8%). Ten patients (3.8%) with a full sensation and slight lactorrhea were classified as having moderate breast engorgement and were considered to have had only fair results. These symptoms occurred on the sixth or seventh day post partum. No patient was considered to have had poor results, since none had severe engorgement, recurrence of lactation, or untoward side effects. Thus, the author considers his plan the method of choice in the suppression of lactation.

PEDIATRICS

Prophylaxis Against Group A Streptococci in Rheumatic Fever The Use of Single Monthly Injections of Benzathine Penicilli G. G. H. Stollerman, J. H. Rusoff and I. Hirschfeld. New England J. Med. **252:**787-792 (May 12) 1955 [Boston].

Monthly injections of benzathine penicillin G were given t 145 patients with rheumatic fever in order to prevent recurrences. The patients ranged in age from 6 to 16 years and ha had an attack of acute rheumatic fever within 18 months at th time prophylaxis was initiated. At each clinic visit (every fou weeks) throat cultures were made, blood was obtained fo determination of antistreptolysin O titer and erythrocyte sed mentation rate, and at six-month intervals electrocardiogram were obtained and fluoroscopy was performed. Patients wh failed to keep a clinic appointment were seen within 48 hour by a visiting nurse, who administered benzathine penicillin an obtained throat swabs and blood specimens. In addition, th nurse investigated reported illness and made throat culture when respiratory infection was encountered. A physician mad a home visit when symptoms suggestive of rheumatic fever or related complication were reported. Benzathine penicillin was injected in a dose of 1,200,000 units contained in a volum of 2 cc. This dose was supplied in a disposable cartridge an was injected deeply into the upper outer quadrant of the buttoc Treatment was continued from September, 1952, to Augus 1954. In addition to the outpatients treated, 265 patients ho pitalized in the acute and convalescent stages of rheumati fever received single monthly injections of 1,200,000 units benzathine penicillin G. No recurrences of rheumatic fever wer observed in the 145 patients who received monthly intramuscul injections of benzathine penicillin G, and only 4 patients gav evidence of recurrence of infection with group A streptococ during the period of study. Of 74 patients who had clinicall apparent rheumatic heart disease on admission to the study, were reclassified as having no heart disease at the end of th study when organic murmurs had disappeared and heart siz had reverted to normal. Five additional patients showed im provement in cardiac status on the basis of the disappearance an organic murmur or return of heart size to normal. Evidenc of progression of heart disease appeared in only three patient a new organic murmur appearing in two and progressive cardia enlargement in the other. A total of 4,871 injections of benz thine penicillin G was administered to 410 patients. The averag number of injections per patient was 12. Most patients exper enced deep muscle soreness and tenderness that lasted for on to three days. This reaction was usually accepted without undu complaint. Only one patient dropped out of the study solely fo this reason. Reactions assumed to be due to penicillin hypersensitivity occurred in five patients. The annual recurrence rat of rheumatic fever (in New York) was about 15% in the year 1936 to 1942, when antistreptococcic prophylaxis was not generally used. The annual rate of recurrence in patients who received either sulfadiazine or penicillin by mouth in other New York clinics was 2.3%, representing a decrease of 85%. The total absence of recurrences in the group treated with benzathine penicillin G may be significant, but an adequate comparison of the various forms of prophylaxis will require more extensive observations on larger numbers of patients. The daily oral administration of sulfonamides or penicillin has the disadvantage that patients are apt to forget to take their medication regularly, and for this reason monthly injections of 1,200,000 units of benzathine penicillin G afford a more reliable method of prophylaxis against recurrences of rheumatic fever.

The Single Approach to Streptococcic Prophylaxis. R. A. Tidwell. Northwest Med. 54:467-471 (May) 1955 [Seattle, Wash.].

Benzathine penicillin, a highly insoluble salt of penicillin, has been demonstrated as the most efficient agent for the production of penicillin blood levels that are required for the prophylaxis of respiratory infection by beta-hemolytic streptococci. This drug is now recognized as indispensable to the long-term management of patients with a history of rheumatic fever. Control of the Streptococcus has been achieved by giving one tablet or teaspoonful daily or one injection per month. This constitutes the "single approach" to streptococcic prophylaxis. Tidwell instituted such a prophylactic program in 1952, reporting observations on an initial group of 59 patients in *Northwest Medicine* (54:470 [May] 1954; abstracted in *J. A. M. A.*, **156**:87 [Sept. 4] 1954). One 200,000 unit tablet of benzathine penicillin was given daily. The present report is concerned with the continuation of the prophylactic program in 34 of the original 59 patients. This group includes 7 with congenital heart disease, 11 with rheumatic fever or rheumatic heart disease, one with asthma, 6 with recurrent respiratory infections, one with nephritis, and 7 siblings. One child, who, owing to an oversight, was not included in the program throughout the summer of 1953, had a strongly positive culture for beta-hemolytic streptococci, type X, on return. Despite the rather constant exposure of all the patients and the various intercurrent infections experienced by most, throat cultures taken at monthly intervals or less throughout the course remained consistently negative for beta-hemolytic streptococci except in two patients, in one of whom the organism temporarily appeared in the throat twice when medication was interrupted, and in one whose throat was cleared promptly by doubling the dose. The presence of tonsils did not interfere with effective prophylaxis. There was no recurrence of rheumatic fever, evidence of subacute bacterial endocarditis, or aggravation of renal disease or asthma in the children ill at the start of the program. No early or late suppurative or nonsuppurative sequelae followed any of the infections that occurred in this series. Benzathine penicillin was accepted willingly by all of the children. No evidence of hypersensitivity or drug resistance developed.

Control of Group A Streptococcal Infections and their Sequelae. L. W. Wannamaker. Journal-Lancet 75:197-214 (May) 1955 [Minneapolis].

There no longer seems to be any reasonable doubt concerning the importance of group A streptococcic infections in the development of acute rheumatic fever and acute glomerulonephritis. In spite of this undeniable relationship, the pathogenesis of these diseases is still not clear. Variation in host response is well recognized but poorly understood. The antigen-antibody theory remains a fascinating hypothesis, but definite proof of its role in the pathogenesis of acute rheumatic fever or acute nephritis has not been produced; furthermore, the possible importance of bacterial hypersensitivity is not known. Recent studies have attracted attention to the significance of strain variation in causing acute glomerulonephritis and to the importance of the persistence of the infecting Streptococcus in the pathogenesis of acute rheumatic fever. At present, the control of the two diseases can best be accomplished through the control of acute streptococcic infections. Adequate treatment of these infections with penicillin prevents acute rheumatic fever and probably reduces the incidence of acute glomerulonephritis. For therapy to be adequate, the organism must be eradicated. This seems to depend primarily on the length of time treatment is continued. Continuous prophylaxis with either sulfadiazine or penicillin prevents rheumatic recurrences by preventing streptococcic infection. Prophylaxis should be continued as long as risk of infection or cardiac damage is great. Complete control of streptococcic infections and their sequelae cannot be expected from the use of antimicrobial agents. The difficulties of differential diagnosis of upper respiratory infections and the frequency of subclinical and atypical streptococcic infections make this impossible. In addition, the long-term effects of the repeated use of these agents are not known. Further advances in the prevention of these diseases will depend on additional knowledge of their pathogenesis and continued inquiry into modes of spread and immunizing methods.

Chlorpromazine in the Control of Vomiting in Children: Preliminary Clinical Evaluation. C. W. Daeschner, J. L. Clark, G. Y. George and R. A. Frankel. A. M. A. Am. J. Dis. Child. 89:525-530 (May) 1955 [Chicago].

Chlorpromazine hydrochloride will control vomiting in adults. The studies described in this paper were concerned with ascertaining effective dosage schedules for children, evaluating therapeutic efficacy, and observing side-effects. During 18 months, 100 clinical trials of chlorpromazine were carried out in infants and children, ranging in age from 6 weeks to 14 years, the majority being under 5 years. Vomiting was caused in 64 of the children by gastroenteritis either nonspecific or associated with acute infections. Other causes were: chalasia of the esophagus, ketogenic diet, diabetes mellitus with acidosis, irradiation therapy for such conditions as leukemia, lymphosarcoma or other malignancies, chemical gastritis due to acetylsalicylic acid therapy, pyloric stenosis, terminal osteosarcoma, postacute bulbar poliomyelitis, appendicitis, and encephalitis. The chlorpromazine was given intramuscularly, by mouth, or in the form of suppositories. Some patients were treated with more than one dosage schedule in an effort to determine the most effective dose range. The intramuscular injections consisted of a solution in isotonic sodium chloride solution ranging in concentration from 1 to 5 mg. per cubic centimeter. The syrup contained 2.5 mg. per cubic centimeter (10 mg. per 4 cc.), and the tablets contained 5, 10, or 25 mg., depending on the dose desired. The suppositories contained from 25 to 50 mg. In 83 of the patients the response was excellent or good. In an additional nine there was a decrease in the vomiting, but the role of chlorpromazine was not definite. In eight patients no clinical improvement was noted. Although toxicity was not a significant factor, since chlorpromazine is a new drug the following precautions should be observed: (1) in patients receiving the drug for more than a few days the possibility of agranulocytosis should be considered; (2) it would seem injudicious to treat patients known to have liver disease or jaundice with chlorpromazine, and the drug should be discontinued in any patient in whom jaundice appears; (3) a helpful soporific effect is a common companion of effective chlorpromazine therapy; pharmacological studies have shown that when chlorpromazine is given concomitantly with central-nervous-system-depressants it may potentiate their effect; and (4) the cause of vomiting should be determined prior to therapy with chlorpromazine, since the latter may mask diagnostic or prognostic signs and symptoms. Its use as an antiemetic in central-nervous-system injury or intestinal obstruction is debatable. Chlorpromazine is an effective antiemetic agent for the symptomatic control of vomiting in children. It appears to have a wide range of usefulness.

Use of Cobalt in Some Common Anemias of Childhood. B. L. Coles. Arch. Dis. Childhood 30:121-126 (April) 1955 [London, England].

In view of the unsatisfactory response to iron of certain common anemias in childhood, a series of patients was treated with cobalt to see whether this substance would prove a satisfactory substitute for iron in refractory cases. Fifty children were treated, and all had types of anemia usually showing a poor response to iron, liver, and other hemopoietic agents. There were 31 children in whom anemia was associated with infection; 10 were anemic premature infants; and three were infants with Rh incompatibility, who showed a residual anemia in spite of transfusions. One patient had severe physiological anemia, and in one anemia developed after Ramstedt's operation, although there was no evidence of gastric hemorrhage. The remaining patients comprised twins with a fairly severe anemia of unknown etiology and a patient with erythrogenesis imperfecta. This last patient was the only one who failed to respond to cobalt therapy. Cobalt sulfate was given by mouth in daily doses of 20 or 25 mg. Treatment was generally continued for about three weeks. No toxic effects were observed with these doses. In an effort to elucidate the still unknown mode of action of cobalt therapy in anemia, marrow punctures were made in 12 children before and after treatment. In six of these anemia was associated with infection and six were premature infants. All 12 responded satisfactorily as far the the peripheral blood was concerned. Nine showed a rise in the total erythroid precursors in the marrow, associated with a fall in the myeloid/erythroid ratio. Erythroid marrow hyperplasia suggests that one action of cobalt is a direct stimulation of the marrow erythroid tissue. Similar changes in the erythroid tissue have been observed by others who used cobalt in anemia. The reticulocyte response to cobalt was not dramatic.

Technical Note on Intrafunicular Transfusion in Treatment of Asphyctic Shock of Newborn Infant. G. Ferraris. Minerva ginec. 7:312-315 (April 15) 1955 (In Italian) [Turin, Italy].

Transfusion into the umbilical vein of newborn infants with severe asphyxia aims at checking the vascular hemodynamic imbalance, which is believed to be the main cause of the shock that accompanies this condition. The standard procedures used in the resuscitation of the newborn infant—aspiration of the respiratory pathways, heating, and administration of oxygen—are also carried out concurrently. At the University of Perugia these procedures are carried out by four trained and experienced persons who work as a team and who can be ready to start in less than one minute after the delivery. A no. 9 catheter, 14 to 16 cm. in length, is threaded through the umbilical vein, and the blood-containing syringe is connected to the other end of the catheter. The average quantity of blood administered varies from 30 to 60 cc., according to the infant's weight, muscle tone, cardiovascular condition, and quantity of blood lost. Immediately after the transfusion of a few cubic centimeters of blood, a sudden improvement in the general condition is observed together with the first respiratory movements. This sudden improvement has been ascribed to stimulation of particular vascular reflexes or a direct mechanical action in the blood stream.

Ophthalmia Neonatorum. H. L. Ormsby. Canad. M. A. J. 72: 576-580 (April 15) 1955 [Toronto, Canada].

In a study of 8,418 newborn infants there were three cases of gonococcic ophthalmia among 1,703 receiving two drops of Sulmefrin solution in each eye at birth, one among 3,125 receiving one drop of 1% silver nitrate solution, and none among 1,570 receiving one application of 10% sodium sulfacetamide ointment. Among 2,020 infants receiving no prophylaxis at birth there were five cases of gonococcic ophthalmia. Mild chemical conjunctivitis was seen in most infants receiving 1% silver nitrate prophylaxis. This cleared within 48 hours, and no other sequelae were observed. Inclusion conjunctivitis occurred in each series and did not appear to be influenced by any of the prophylactics. All cases of this disease ran a benign course, and many cleared spontaneously without treatment. The intramuscular injection of penicillin into the mother during labor would seem to be the best prophylaxis of gonococcic ophthalmia in the infant, but the danger of hypersensitivity reactions prohibits routine use of this method. The same difficulty applies to treatment of the infant with intramuscularly administered penicillin. It is concluded that, although certain new areas of therapy, such as the use of prophylactic agents in ointment base, are worthy of study, the time-tested procedure of applying 1% silver nitrate solution to the conjunctival sac at birth is an efficient prophylactic against gonococcic ophthalmia.

Nephrosis and ACTH: Special Reference to Humoral Changes Observed in Four Cases. J. Meneghello R. and F. Monckeberg B. Rev. chil. pediat. 26:1-8 (Jan.) 1955 (In Spanish) [Santiago, Chile].

Four patients between the ages of 1 and 4 years with nephrosis of from two to six months' duration were observed. All patients had intense edema, anasarca, ascites, and marked albuminuria. The serum proteins were low with decreased albumins and increased alpha and beta globulins. The serum cholesterol was increased. Hematuria was found in three patients. ACTH was given intravenously in doses of 7 to 15 mg. at intervals of hours for about 10 days. In the course of treatment the intak of salt was restricted and penicillin or chloramphenicol wa administered. All patients responded with an abundant diuresi a great loss of body weight, complete disappearance of edem and albuminuria, absence of sodium retention in urine, elimin tion of sodium and potassium in the urine in normal ratio, co version of the changes of serum proteins into normal pattern and control of all the other humoral derangements and clinic symptoms of nephrosis. The complications observed include transient moderate uremia in all patients, moderate hypertensio in some, and hypertension with cardiac insufficiency that ma discontinuation of the treatment necessary in one patien Marked natremia occurred during intense diuresis in one patien and it was controlled by administration of sodium. Remissio lasted for three and six months, respectively, in two patien In the other two patients follow-up observations were not mad Although the response to the intravenous use of ACTH prompt and satisfactory, the treatment should not be used as routine. It is indicated for hospitalized patients and for patien who respond to the intramuscular treatment with a poor diures The treatment may be discontinued as soon as an abunda diuresis appears. The normalization of humoral changes aft ACTH diuresis observed by the authors suggests that ACT controls the hydrosaline imbalance that is the primary cause all humoral derangements and clinical symptoms of nephros

OPHTHALMOLOGY

Macular Holes in Retinal Separations: Their Significance a Their Surgery. A. H. Keeney. Am. J. Ophth. 39:648-653 (Ma 1955 [Chicago].

Macular holes are due to contusion or degeneration but either event cystic degenerative changes precede the typical ho formation. Simple, degenerative holes do not lead to retin separation. Proper retinal position is maintained in the presen of typical, punched-out lesions when: (1) the hole is a cyst wi an intact inner wall; (2) such a macular cyst has ruptured throu its inner wall only, thus leaving an intact outer wall; or (perimacular adhesions between the choroid and retina have be created by local inflammation. Macular holes are rarely t cause of retinal separation, in which case they must be comple holes. More commonly they are incomplete and incidental the pathogenesis of separation. When macular holes are inco plete they should not be subjected to operation with its attenda loss of valuable perimacular acuity. Sealing of complete macul breaks should be done with small, partial-penetrating electrod using low current, directed precisely to the edges of the hol

Hereditary Degeneration of the Macula Occurring in Five Ge erations. C. T. Davis and R. W. Hollenhorst. Am. J. Opht 39:637-643 (May) 1955 [Chicago].

Degeneration of the macula of each eye was discovered in persons in a kinship of 148 members, belonging to five gener tions. This family was discovered when two young women, year-old first cousins, presented themselves for examination the Mayo Clinic because of pregressive loss of visual acuity i each eye since early childhood. The visual defects in each these two young women were identical. As they were questione the existence of many similar visual defects among their kin wa disclosed. Since virtually the entire family resided in centra Wisconsin, it was possible to make a complete genetic study A macular lesion was responsible for the visual disability ob served among members of this family. The lesions found i the maculas of persons of about the same age were almos identical in appearance, and the patients' complaints were sim ilar. The age at onset of manifest visual disability varied from early childhood to adolescence. The lesions were progressiv and were symmetrical in each eye. A central scotoma wa responsible for the impairment of vision. Marked impairmen of color discrimination was associated with the lesions. Each patient had some degree of day blindness, but none had an associated cerebral lesion. The authors believe that the course of the disease, the appearance of the lesions ophthalmoscopically, and the other findings in the ocular examination place the disease in the group of heredofamilial degenerations of the macula without cerebral involvement; that is, Sorsby's macular dystrophy. The defect is transmitted as a dominant trait with complete penetrance.

Laboratory Observations on the Ocular Use of Tetracycline. J. W. Hallett, K. Naib and I. H. Leopold. Am. J. Ophth. **39**:691-696 (May) 1955 [Chicago].

It has been claimed that tetracycline, chlortetracycline, and oxytetracycline have the same broad-spectrum activity against gram-negative and gram-positive bacteria, certain viruses, and rickettsial infections. Solutions of tetracycline in 0.85% sodium chloride maintained their antibacterial activity undiminished after three weeks' storage at 5 C, whereas similar preparations of chlortetracycline and oxytetracycline commenced to deteriorate after from 24 hours to one week of storage. Furthermore tetracycline is said to diffuse readily into body tissues and fluids and to have low toxicity and a wide margin of safety. Since no reports were available on the ocular effects of tetracycline, studies were made on the eyes of rabbits. Summarizing the results of these studies, the authors say that aqueous levels theoretically effective against gram-positive organisms appear up to two hours after intravenous injections of 100 to 150 mg. in rabbits. Small corneal and smaller vitreous levels are found one hour after intravenous injection of 150 mg. The latter dose may, however, be nearly lethal. Subconjunctival injections of 10 mg. per cc. produce adequate corneal and aqueous levels up to four hours and vitreous levels up to one hour. The inflamed eye accepts the antibiotic in larger amounts than does the normal eye. Corneal bath or eye drops in concentrations of 25 mg. per cubic centimeter produce effective corneal levels for four hours. Aqueous levels are adequate up to two hours in the intact and up to four hours in the inflamed eye. Subconjunctival injections in concentrations up to 5 mg. per cubic centimeter are safe; eye drops in concentrations up to 25 mg. per cubic centimeter are harmless; corneal baths in concentrations up to 10 mg. per cubic centimeter are innocuous; and intracameral injections in concentrations greater than 1 mg. per cubic centimeter are dangerous.

Increase in Optic Nerve Lesions in Patients with Tuberculous Meningitis Being Treated with Isoniazid and Streptomycin. G. Janssen and W. Böke. Klin. Wchnschr. **33**:477-479 (May 15) 1955 (In German) [Berlin, Germany].

Studies on 245 children with tuberculous meningitis who were treated between 1948 and 1954 revealed that in those admitted for treatment since the introduction of isoniazid therapy in the second half of 1952, there was a definite increase in optic nerve lesions. Papillary changes taking the form of edematous swelling may correspond to choked disk or optic neuritis, differentiation being possible only by functional tests on the visual acuity and visual fields, which are rarely possible in a patient with severe meningitis, the less so if the patient is a child. When functional tests were possible, signs of optic neuritis were detected, and the temporal atrophies observed in several patients also suggested neuritic processes. Vascular lesions leading to prolonged ischemia may be brought on by perioptic meningitis or by optochiasmatic arachnitis, and rarely a miliary tubercle within the optic nerve may cause a papillitis. Estimates on the incidence of such lesions in tuberculous meningitis vary widely, but the authors believe that the increase in optic nerve lesions and the progression of these lesions to optic atrophy since 1952 must be due to a new factor. Since there is no evidence that the combination of isoniazid and streptomycin is particularly toxic, the authors believe that perhaps the giving of massive doses at the onset is responsible. For this reason they now dispense with the intrathecal administration of isoniazid at the onset, the more so, since with adequate oral doses, isoniazid is known to penetrate into the cerebrospinal fluid.

THERAPEUTICS

A New Antihistamine for Treatment of Various Allergic Manifestations. N. W. Clein. Ann. Allergy **13**:163-168 (March-April) 1955 [Minneapolis].

A new antihistamine, 1-methyl-4-amino-N′-phenyl-N′-(2′-thenyl)-piperidine tartrate (Sandostene), was given to 124 patients with hay fever due to pollen grass and other forms of allergy. The new drug was given alone and in combination with calcium, orally and intravenously, from May through August. All patients under 6 years of age were treated with the syrup of the antihistamine combined with calcium, and all patients over 6 were given the antihistamine in 25 mg. tablets. The average dose of the syrup was one teaspoonful three or four times a day. Two to four tablets daily were given depending on the age of the patient and the severity of the symptoms. One week the average dose was given, followed by one week of rest, and the third week the dose was doubled. Of the 124 patients, 76 had hay fever, 12 hay fever and asthma, 17 eczema, 8 perennial allergic rhinitis, 4 urticaria, and 7 angioneuritic edema with urticaria. The last seven patients were given intravenous injections of Sandostene combined with calcium in doses of 10 cc. The antihistamine was given only to those whose symptoms were not relieved by the grass pollen antigens and other treatment. A group of patients with similar symptoms was used as control. Of the 124 patients, 21 obtained excellent, 38 good, 35 fair, and 30 poor results. Two children had minor toxic manifestations. The best results were obtained in smaller children and in those whose symptoms were caused primarily by inhalants rather than foods. There were no cases of drowsiness, and the author was particularly impressed with the lack of undesirable side-effects. Since this new antihistamine is available in tablet form, in syrup, and in ampules containing the product combined with calcium, the form most suitable for each patient can be chosen. The combination with calcium in syrup and ampules results in a potentiation of the effect on cellular and vascular permeability. Although the new antihistamine, which appears to be more effective than others, is a valuable adjunct in the treatment of various allergic manifestations, specific allergic management is still of primary importance in the control of allergic disease.

The Question of Reactions to Mercurial Diuretics: A Reappraisal. E. A. Brown. Ann. Allergy **13**:131-159 (March-April) 1955 [Minneapolis].

The advent of the newer organic mercurial diuretics, given intramuscularly, subcutaneously, or orally, the increased caution in making dosage schedules, and the awareness of the implications of early minor undesirable side-effects have reduced the number of fatal reactions more than one would expect on the basis of idiosyncrasy to such commonly used drugs. In one clinic 13,000 injections of mercurial diuretics have been given in a four-year period, without any ill effects. One of the author's own patients received weekly injections for more than 10 years, with no adverse effects. When the physician is alert to problems of dosage in relation to the patient's age and weight, to water and electrolyte balance, to side-effects as evidenced by excessive diuresis, and to the possibility of allergic reactions, toxic effects due to large doses should easily be avoided. The small group of truly allergic patients can be recognized and treated with the proper precautions. The history will, if directed towards discovering "drug-reactors," help uncover those who require special handling. Treatment should always be initiated with small doses of 0.2 to 0.5 cc. Intradermal skin tests and patch tests, even on abraded skin, are not dependable. The injection of 0.05 cc. of serum from a patient taking the mercurial diuretic in question (and not sensitive to it) injected intradermally will often result in a wheal, if the recipient is sensitive to the drug. Since normal serum evokes a slight to moderate response, good technique must be used and the results interpreted qualitatively as well as quantitatively. A positive reaction to the test does not mean that the patient cannot tolerate with safety another mercurial diuretic, especially if the same precautions are followed. Choice of a diuretic agent may be directed to different classes of compounds, as well as to different drugs within each class. The routes of administration constitute another basis for choice. Mercurial diuretics are remarkably safe drugs when properly used. Such use, however, requires a recognition of the fact that the patient who needs them presents a dynamic system involving the interplay of a number of physiological and pathological processes, all of which must be taken into account for the maximum safety.

Treatment of Leukemia and Allied Disorders with 6-Mercaptopurine. J. R. Fountain. Brit. M. J. 1:1119-1124 (May 7) 1955 [London, England].

Of 26 patients with leukemia and allied diseases treated with 6-mercaptopurine, a purine antagonist, at the General Infirmary in Leeds, England, since June, 1953, 13 had acute leukemia, 7 chronic myeloid leukemia, 2 chronic lymphatic leukemia, 2 multiple myeloma, one mycosis fungoides, and one erythroderma secondary to an underlying reticulosis of undetermined type. The dose of the drug was based on that suggested by Burchenal, the initial dose being about 2.5 mg. per kilogram of body weight. Thus a 5-year-old child was started on 50 mg. and an adult on 150 to 200 mg. per day. The same dosage scheme was used both for patients with acute and those with chronic leukemia, and in all patients, the daily amount was divided in doses of 25 or 50 mg. given over 24 hours. Seven of the 13 patients with acute leukemia responded to the treatment: 5 had complete clinical and hematological remissions, and 2 had partial remissions. The remissions were only temporary, and resistance to further therapy with 6-mercaptopurine eventually resulted. Of the seven patients with chronic myeloid leukemia, one died of cerebral thrombosis a week after treatment was instituted. The other six patients showed a varying response, with increase in well-being, activity, appetite, and weight in four, and diminution in the size of the spleen and lymph nodes in five. The leukocyte count fell in all six patients, and erythropoiesis improved in two. One patient in the acute terminal phase had a remission lasting four and a half months. The two patients with chronic lymphatic leukemia, the two with multiple myeloma, and the patient with reticulosis of the skin did not respond to the treatment, but the patient who had mycosis fungoides obtained some improvement. Six-mercaptopurine is of low toxicity, and no serious complications followed its use. Whether patients who have a complete remission should receive a daily maintenance dose of 6-mercaptopurine remains to be answered, but from the author's limited observations it seems likely that maintenance therapy may not greatly prolong the remission. Continuous therapy seems essential in chronic myeloid leukemia if the beneficial effect of the drug is to be maintained. One of the patients was symptom-free and fully active for six months on a daily maintenance dose of 50 or 100 mg. In the absence of maintenance treatment a clinical and hematological relapse may follow the discontinuation of the drug within a month. With the knowledge that 4-aminopteroyl glutamic acid (aminopterin) and amethopterin, corticotropin and cortisone, and 6-mercaptopurine may all produce clinical and hematological remissions in acute leukemia, it seems desirable to give patients the advantage of such chemotherapy; sequential use of these drugs may offer several months of useful life. Although more patients with chronic myeloid leukemia must be treated before the ultimate value of 6-mercaptopurine is known, the initial observations suggest that it will have its place in the management of this disease.

Malarial Therapy in the Nephrotic Syndrome. O. G. Shaper. Brit. M. J. 1:1132-1135 (May 7) 1955 [London, England].

Four men and three women between the ages of 18 and 52 years with the nephrotic syndrome, i. e., with edema, proteinuria, and hypoalbuminemia, but without hypertension, nitrogen retention, or electrolytic disorder, and without an appreciable number of red blood cells in the urine, were given malaria therapy at the tropical disease center of the Sefton General Hospital, in Liverpool, England. The patients had failed to respond to more conservative forms of treatment. Six of the seven patients were infected with Plasmodium vivax by intravenous inoculation, and one patient was infected with Plasmodium ovale. The patients
were allowed to have as many chills as they were capabl
withstanding. Three of the seven nephrotic patients had a
nounced remission of symptoms for one year. The improven
in two other patients could not be associated with the mal
therapy. The last two patients died of their basic condition,
as they were both severely ill and the malarial paroxysms
poor or curtailed in number, it would be unfair to say
malaria therapy had failed. The satisfactory results obtaine
three patients encourage the continued use of malaria treatn
in nephrotic patients who do not respond to more conserva
treatment.

**Toxic Hepatosis with the Aspect of Intrahepatic Obstruc
Type Jaundice After Administration of Chlorpromazine (Lar
til), Atophan, Arsphenamine and Methyltestosterone.** C. M
and J. R. Rüttner. Schweiz. med. Wchnschr. 85:445-448 (Ma
1955 (In German) [Basel, Switzerland].

The occurrence of jaundice after the administration of ch
promazine (Largactil) is described in two psychotic women,
30 and 83 respectively. The total dose of chlorpromazine gi
to the first patient was 1.8 gm., and that given to the second
tient was 2.5 gm. The clinical aspect of the younger woman
responded with that of obstructive jaundice in three pati
reported on by Van Ommen and Brown (J. A. M. A. 157:
[Jan. 22] 1955). The 83-year-old patient died of pneumonia
cardiac decompensation and autopsy revealed cirrhosis of
liver associated with icterus. A toxic hepatosis resulted from
administration of chlorpromazine in the first patient, whil
the second patient cirrhosis of the liver was imminent but
not recognized when chlorpromazine was administered. The
currence of obstructive jaundice after the administration of o
drugs such as phenylquinoline carboxylic acid (Atophan-
chophen), arsphenamine, and methyltestosterone has been
ported in the literature. The various observations of chlor
mazine-induced icterus suggest caution in the administratior
the drug to psychiatric patients. Biliary stasis as a possible
toward reaction to the drug should not be considered harml
Evaluation of the degree of severity of the chlorpromaz
induced icterus should not be based on the result of the
tein flocculation or galactose tests, but on prothrombin ti
alkali phosphatase level, and cholesterol. The daily maximal d
of the drug should be reexamined by the psychiatrists.

**Serum Penicillin Concentration After Peroral Administrat
of Penicillin Combinations With and Without Probenecid.**
Lind and C. Trolle-Lassen. Ugeskr. læger 117:519-522 (A
28) 1955 (In Danish) [Copenhagen, Denmark].

The main investigations were carried out in well persons
two age groups, 20 to 25 and 68 to 78. It was found t
dibenzylethylendiamidinedipenicillin (DBED) by the mouth d
not offer any therapeutic advantage over ordinary benzyl pe
cillin. A certain therapeutic effect is ascribed to the high init
serum concentration of benzyl penicillin. Simultaneous pero
administration of these penicillin combinations and probene
gives a longer lasting therapeutic serum penicillin concentrati
than the administration of penicillin alone, so that oral admin
tration every eight hours seems to suffice. The older age gro
showed a higher and longer lasting serum penicillin concentrati
than the younger age group, which is explained by reduction
renal function due to age.

**A Year's Clinical Experience with Spiramycin in Infectious Di
eases.** A. Darbon and R. Crosnier. Presse méd. 63:681-683 (M
7) 1955 (In French) [Paris, France].

The new antibiotic, spiramycin, was recently extracted fro
Streptomyces ambofaciens. The authors used it on about 10
patients. Spiramycin has good therapeutic activity on gram
positive organisms. Its activity was as good as, and sometime
better than, that of the better-known antibiotics. It was excel
lently tolerated and was definitely superior in this respect to othe
antibiotics as far as oral administration was concerned. Onl

ne patient had a gastrointestinal reaction. The daily doses were f 2, 3, and sometimes 4 gm.; the 3-gm. dose appeared to be the est. There was a certain amount of disparity between the drug's tivity in vitro and in vivo. In two patients, spiramycin proved ore efficient than could have been expected, judging from boratory tests, and in a third, the drug's efficacy was disapinting compared to what was seen in vitro.

se of **Zetacillina in Surgical Infections.** M. Rubino. Clinica :221-223 (No. 4) 1954 (In Italian) [Bologna, Italy].

"Zetacillina," a drug in which penicillin is combined with a lfonamide, was used in the treatment of 27 patients with rgical infections. From 6 to 12 capsules, each containing ,000 units of penicillin and 0.25 gm. of the sulfonamide, were ven to the patients daily for varying lengths of time. The drug nefited most of the patients. The results were good in 20, ediocre in 5, and poor in 2. The use of this drug is contradicated in conditions in which the intestinal absorption is ered, in the immediate postoperative course, and in intestinal clusions, because in such instances therapy should be given the parenteral route.

ATHOLOGY

thology of Cerebral Palsy: II. Cerebral Palsy Due to Encephclastic Processes. A. Towbin. A. M. A. Arch. Path. 59:529-2 (May) 1955 [Chicago].

Twenty-three cases of cerebral palsy, derived mainly from population of the Columbus State School, Ohio, between 50 and 1954, were studied at autopsy by Towbin. Three basic thological types were evident in this group. Developmental fects of the brain accounted for the neurological disorder in patients who were reported on in a previous paper (abstracted, *A. M. A.* 158:888 [July 9] 1955). Of the other 17, antecedent stemic disorders, such as neonatal anoxia and erythroblastosis alis, were considered to be the mechanism of damage in 8; rebral palsy was caused by mechanical injury to the brain, drocephalus, and other intrinsic local defects of the brain in cases. Cerebral palsy is the result of a heterogeneous group of thological processes. The lesions of the brain in this disorder incurred during fetal and infantile life; in most cases the ramidal or extrapyramidal system is involved. Only by corlating clinical observations with the findings in the brain at topsy can a comprehensive appraisal of the processes in cereal palsy be obtained. Further resolution of the problem of usation in cerebral palsy is of immediate importance as a quisite to the successful pursuit of prophylaxis and treatment. is increasingly evident that cerebral palsy in a significant prortion of cases is related to systemic disorders of the fetus and fant. Consequently, the problem of cerebral palsy becomes creasingly the province of the general pathologist.

ntibody Production by Spleen in Vitro: I. Influence of Cortine and Other Chemicals: II. Correlation of Weight of Rabbit, eight of Spleen, and Level of Antibody Produced in Vitro. M. Mountain. J. Immunol. 74:270-277 and 278-280 (April) 55 [Baltimore].

The production of H-agglutinin in vitro by spleen taken from bbits immunized with typhoid vaccine was studied. Spleens moved from the animals four days after a single intravenous jection of vaccine were minced, and a culture of minced spleen rved as the basis for the author's test system. Antibody production in culture continued for at least three days. The reproucibility of the test system was evaluated statistically in order assay the effect of the addition of various inorganic and rganic chemicals, including vitamins and hormones, on antiody production. Antibody formation in vitro required oxygen nd was suppressed by sodium cyanide in final concentrations of rom 10^{-2}M to 10^{-4}M, and by salts of the heavy metals at inimal concentrations indicated: manganous sulfate 10^{-3}M, erric chloride 10^{-2}M, and cupric sulfate 10^{-4}M. Antibody formation in vitro was also suppressed in the presence of 100 mM. sucrose, by the "essential" amino acids at 30 mM. (combined total concentration) and by the reducing substances: reduced glutathione in a concentration as low as 15 mM., cysteine in a concentration of 15 mM. or lower, ascorbic acid in a concentration of 15 mM. or lower, as well as by cortisone in a concentration of 32 mg. per 100 cc. or more. With the exception of glutathione, and possibly sucrose, none of these substances, at concentrations that were found to be inhibiting, altered the antibody titer when incubated with immune serum. Thus the various chemicals inhibited some phase of antibody formation by surviving cells in culture rather than by destruction of antibody once formed. Eleven rabbits of weights varying from 3 to 6 kg. were each given a single intravenous injection of typhoid vaccine. Four days later the rabbits were bled from the heart with the aid of pentobarbital anesthesia and the entire spleen was removed. The weight of the spleen and the weight of the rabbit showed a positive correlation. Furthermore the weight of the spleen, as well as the weight of the rabbit, showed a positive correlation with an index of the antibody-forming capacity of a given mass of the spleen in vitro. These results indicate that in selecting animals for study of antibody production in vitro not only will a heavier spleen be obtained from a larger animal but a given fragment of such an antibody-producing tissue can be expected to give a higher yield of antibody. The observed correlation between the size of the spleen and its capacity (per unit weight) to produce antibody introduces a new parameter for the study of the cells responsible for antibody production.

RADIOLOGY

Physiological Aspects of the Tumoral Circulation Proper in Ten Cases of Glioblastoma Multiforme. V. A. Fasano and G. Broggi. Minerva chir. 10:215-219 (March 15) 1955 (In Italian) [Turin, Italy].

Ten patients with glioblastoma multiforme were studied by angiography. In most of these patients the angiograms revealed a direct arteriovenous communication. The presence of a neoplasm, through which these communications were seen, modified the cerebral hemodynamics. The result was slackening of the cerebral circulation, the extent of which depended on the morphological aspect of the neoplastic vascular network. This altered circulation became more evident on the angiograms that showed the circulation within the neoplasm. In some of these patients the angiograms failed to demonstrate a vascular system within the glioblastoma. Histological studies of the removed tumors seemed to indicate that this failure occurs more frequently in patients in whom such changes as hemorrhage, necrosis, vascular proliferation, or cysts are present within the neoplastic tissue.

New Agents for Cholecystangiography (Telepaque, Biligrafin). T. Denstad. Tidsskr. norske lægefor. 75:259-263 (April 15) 1955 (In Norwegian) [Oslo, Norway].

The new agents for cholecystography, Telepaque for peroral use and Biligrafin for intravenous use, have been tested in Aker Hospital for about a year. They contain three atoms of iodine in the molecule, give a denser gallbladder shadow, and allow roentgenologic presentation of the bile ducts. With Telepaque this depends on a functioning gallbladder that can concentrate the bile containing the contrast medium, but the bile ducts can be filled with the contrast medium even though the gallbladder has been removed or its concentration ability is reduced (cholecystitis) if Biligrafin is used. Besides the detection of stones in the common bile duct study of the bile duct dyskinesias is made possible. For examination especially of the bile ducts Biligrafin should be applied, while Telepaque affords better information about the condition of the gallbladder. Side-effects are few. Grave liver affection, marked jaundice (but not slight jaundice), acute nephritis, uremia, and gastrointestinal disturbances are contraindications.

RINGWORM

To the Editor:—*A family recently acquired a cat; it also had a dog. Subsequently the family developed ringworm of the body; three of the children also had a small spot or two on the scalp. The dermatologist diagnosed the children's ringworm as due to Microsporum audouini. He x-ray-epilated two of the children; this was followed by local treatment. Later animal ringworm M. canis was recovered by culture from the cat and the dog and all the lesions on the children. 1. Can the difference in the two types be told by the amount of fluorescence under Wood's light? 2. Should patients with scalp involvement caused by animal ringworm of the scalp be epilated, or should more conservative treatment be tried first? 3. Is animal ringworm of the scalp more easily cured than the usual type due to M. audouini? None of these lesions was of the kerion type. Please indicate treatment for both types of ringworm on the scalp and on the body.*

Douglas P. Arnold, M.D., Buffalo.

Answer.—1. No. 2. Conservative treatment should be tried first. 3. Yes. Apply 5% salicylanilide in a "greaseless" base daily, shampoo frequently; under Wood's light, at frequent intervals, epilate the diseased hairs with a forceps and have the youngster wear a cap constantly. If there is no progress after a reasonable period of time (two to three months), the hairs should be epilated by x-rays by somebody trained in the technique. This routine may be used for either type of ringworm of the scalp. The body types usually respond to treatment with benzoic and salicylic acid (Whitfield's) ointment diluted to one-eighth to one-fourth strength and applied several times daily.

CHEST PAIN AND TIC DOULOUREUX

To the Editor:—*A woman 59 years old weighing 140 lb. (63.5 kg.) has always had good health except some sinusitis and an attack of tic douloureux eight years ago, which was fairly well controlled for three years by injections. Finally she was operated on for the condition, with satisfactory results. Shortly after the operation she began to have pains in the left side of the chest. They were trigger pains, which became more painful, and were only relieved by intercostal nerve root injection (during the injection an accident occurred, a collapse of the left lung); the pain was relieved, however. During the past two weeks she is suffering recurrence of the chest pain with more frequency and intensity. Every classical symptom of tic douloureux is present—only the intercostal nerves on the left side, the 4th and 5th nerves as near as I can determine—are involved. It is impossible to adequately examine the area because of starting the pain. Please give information on treatment for the condition.*

J. W. Wentz, M.D., Pataskala, Ohio.

Answer.—Major neuralgia of the type that occurs in the trigeminal and glossopharyngeal nerves (trigeminal neuralgia and glossopharyngeal neuralgia) does not occur in any other nerves in the body. The intercostal neuralgia that is described here must have some other explanation. The nerve may be involved by a tumor, by a herniated intervertebral disk, by an arthritic spur, or by some other condition, such as a previous herpes zoster. Without knowing the cause for the condition in this case, it would not be possible to recommend treatment. The first indication is a thoroughgoing investigation and diagnosis.

ATROPHIC RHINITIS

To the Editor:—*What can be done for a woman over 50 years of age who has a gradual loss of sense of smell, with no antecedent disease except for a dry nose?* *M.D., Illinois.*

Answer.—A patient over the age of 50 who has had a dry nose is probably suffering from atrophic rhinitis. This condition is characterized by an atrophy of the mucous membrane of the nose, including the mucus-producing glands. The symptoms vary from a mildly dry nose to a severe crusting and foul-smelling condition. There is an associated atrophy of the olfactory mucosa including the glands of Bowman, which produce a secretion into which the odoriferous particles are normally imbedded in the process of olfaction. There is no known curative treatment for atrophic rhinitis or the associated anosmia. For the common nasal preparations used for symptomatic relief of atrophic rhinitis the reader may refer to any of the common textbooks of otolaryngology.

BISMUTH SUBNITRATE

To the Editor:—*Is there any clinical evidence that bismuth subnitrate in ointment form applied topically to the skin is absorbed through the intact skin and might cause nitrous oxide poisoning?*

M.D., Pennsylvania.

Answer.—No; nor is such a reaction likely to occur because the subnitrate radical, if it converts, would probably convert in the direction of a nitrite. Nitrite poisoning has been reported from high doses of bismuth nitrate administered orally—doses of 30 to 60 gm. within a 24 hour period; it is inconceivable that such an amount could be absorbed from an ointment.

DEATHS FROM ANTIBIOTICS

To the Editor:—*In an inquiry on "Differentiation Between Viral and Bacterial Respiratory Infection" in* The Journal *on May 21, 1955, page 239, one question raised was: "What is the actual number of deaths reported as directly or indirectly attributable to antibiotics in general and to penicillin in particular?" I would like to comment on this question. A recent search of the literature revealed a total of 48 anaphylactic deaths reported from penicillin and 34 deaths from aplastic anemia following chloramphenicol administration (Hussar, A. E., and Holley, H. L.: Antibiotics and Antibiotic Therapy, New York, the Macmillan Company, 1954). Fatalities reported from micrococcic (staphylococcic) enteritis, fungal or other superinfections, periarteritis nodosa, renal toxicity, intrathecal administration, and other causes have not been counted but may be roughly estimated at about 100 cases. These figures, however, do not represent the true incidence of fatal antibiotic reactions, since a considerable number of cases remain unreported. I know of at least six antibiotic fatalities that were never reported. Certainly, many other physicians have similar knowledge. It is a fair estimate then, that probably several hundred persons have died from antibiotic administration. True, this incidence is a very small percentage of the total number who have received antibiotics. However, it would be erroneous to minimize the charge of promiscuity in the use of a therapeutic agent solely because of the low percentage of fatal reactions. No matter how small the statistical figures, they became 100% for those physicians who lost their own children through such accidents. When dealing with human lives, even small risks have to be taken with great caution and, therefore, the risk of antibiotic administration must be well balanced by a justifiable indication for such medication. Peculiarly enough, accidents often hit when unjustified risks are taken. An analysis that I have made of the reported fatalities has revealed that about one-half of these individuals died from unnecessary antibiotic medication.*

The indiscriminate use of antibiotics should be condemned not only because of untoward drug reactions, but also for many other reasons, among which two should weigh heavily: the threat to the future usefulness of present-day antibiotics and the threat to our professional standards.

Montrose, New York.

CANKER SORES

To the Editor:—*I have read with great interest the various letters in Queries and Minor Notes dealing with treatment of canker sores. About a year ago I was privileged to try a new germicide called Clorpactin WCS-90, which is a brand of monoxychlorosene. I have had success in treating 19 cases of canker sores locally with this powerful and apparently nontoxic germicide. A paper on my experiences and results with Clorpactin WCS-90 will be published in the August, 1955, issue of the A. M. A.* Archives of Otolaryngology.

TRANSHEPATIC VENOUS CATHETERIZATION AND VENOGRAPHY

Howard R. Bierman, M.D., Keith H. Kelly, M.D., Laurens P. White, M.D., Alexander Coblentz, M.D.
and
Arthur Fisher, M.D., Duarte, Calif.

The portal venous system has generally been considered inaccessible except at laparotomy. During investigations in man on the relationship of the spleen and the liver in the dynamic physiology of the circulating formed elements of the blood, it became desirable to obtain blood repeatedly from the portal vein during relatively long periods of time. The procedure of direct transhepatic portal venipuncture was conceived in 1951 as a relatively simple clinical method of obtaining portal venous blood for this purpose.[1] The original description of the procedure on 14 patients was preliminary in nature and merely recorded the feasibility for short-term sampling. This report describes an improved technique for transhepatic venipuncture and catheterization of the portal and hepatic veins that has evolved from the experience gained during 144 transhepatic venipunctures performed on 73 patients during the past two years.

MATERIALS AND METHODS

Anatomic Considerations.—The portal vein in the normal adult is about 7 to 8 cm. in length, extending from the level of L-2 to L-3 to the porta hepatis at the junction of L-1 and T-12. Just before the portal vein enters the liver, it divides into a right and left branch supplying the respective lobes.[2] The shorter and thicker right branch of the portal vein divides again shortly after its origin and then subsequently develops extensive ramifications to supply the larger right lobe, which comprises about 60% of the entire liver tissue. The branching of these radicles in the normal liver is of great regularity. The division of the portal vein usually takes place at the level of T-12 in the transverse plane. Most of the branching occurs within a 3 cm. stratum in the anteroposterior dimension and is inclined cephalad to the left at an angle of 15 to 20 degrees, roughly parallel with the lower edge of the anterior border of the liver.[3]

Serial cross sections of the liver in the transverse plane revealed that the largest and most accessible ramifications of the portal vein were slightly above the initial division of the portal vein within an arc of 20 to 40 degrees from the linea alba at the skin surface at the level of T-12 (fig. 1). The introduction of a needle to a depth of 6 to 12 cm. could be reasonably expected to enter one of the major portal radicles if directed within the area described. Since the inferior vena cava lies at a depth of 15 cm. and the major tributaries of the hepatic vein are most often encountered at the level of T-8 to T-10, these structures are avoided if the following technique is employed.

Procedure.—With the use of routine sterile precautions, the portal venipuncture may be done at the bedside or on the x-ray table if venograms are desired. For the patient without an easily palpable liver, a semi-Fowler's position (15-20 degrees) is preferred. In the patient with a liver of approximately normal size, a point 1 cm. below the xiphoid process and 1 cm. to the right of the midline is anesthetized with the injection of 2% procaine hydrochloride deep to and including the parietal peritoneum. The introduction of a few cubic centimeters of procaine over the surface of the liver has produced as much analgesia at the site as has direct injection of the liver capsule or parenchyma. The portal venipuncture needle is then passed through the skin and parietal peritoneum until it reaches the surface of the liver. The needle is poised for a moment while the proper angle of introduction is confirmed. The patient is then asked to take a moderately deep breath and hold it. The needle is advanced rapidly and firmly to the 12 cm. marker, maintaining the selected angle. The needle is released, and the patient is permitted to breathe. The hub of the needle will move in a manner paradoxical to the inspiratory and expiratory excursions of the liver. Fixing the proximal end of the needle firmly while the patient is breathing

deeply increases the hazard of tearing the liver parenchyma. The patient should be cautioned to breathe in a shallow fashion during the remainder of the procedure.

The obturator is removed and gentle aspiration applied as the needle is slowly withdrawn. When the distal opening of the needle lies within a vessel, blood will flow freely into the syringe, although variations due to inspiration and expiration may be expected depending on the venous pressures encountered. The needle should be rotated 360 degrees to determine the position of optimal flow, after which the sliding marker-guard should be adjusted to the skin surface to maintain the exact position of the needle. If the needle is aimed 5 to 10 degrees superiorly from the horizontal, the radicles of the hepatic vein may be entered at the 10 cm. depth. If the needle is introduced to the 15 cm. depth in the true transverse plane, less than 10 degrees from the midline to the right, the inferior vena cava may be entered. In those patients who have hepatomegaly or in whom the liver is depressed inferiorly, the landmarks must be revised. The porta hepatis is displaced inferiorly as the liver enlarges. The optimal site for portal venipuncture similarly moves downward.

A special needle has been devised for portal venipuncture; a no. 16 to no. 18 needle, 15 cm. long, with a distal side opening and tight-fitting obturator has been found most effective. This needle is preferred because of its single cutting edge and directional opening. The proximal end of the needle has a recessed hub so that clotting is minimized. The bore of the needle also fits into the end of a Luer-Lok syringe, and the obturator handle and needle are notched, indicating the direction of the distal opening. The needle may thus be rotated 360 degrees to relieve an obstruction. A sliding guard is also provided to facilitate measuring and maintaining the proper length of the needle during and after the insertion of the needle into the liver.

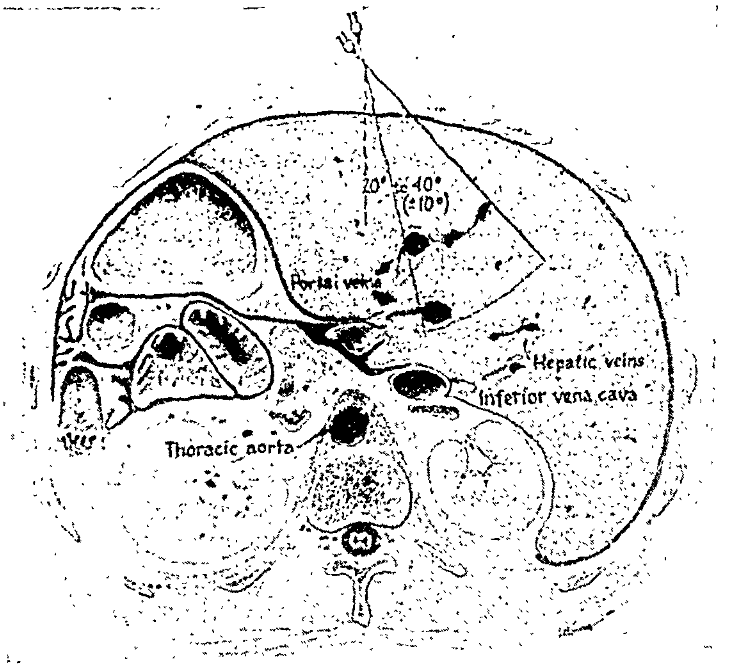

Fig. 1.—Transverse cross section of body at level of 12th thoracic vertebra. Note that the major divisions of the portal vein are contained within a 20 to 40 degree wedge at a depth of 6 to 12 cm. from skin surface.

Catheterization.—Since one of the major goals of this investigation was to obtain portal blood samples repeatedly over prolonged periods, catheterization of the portal vein via the venipuncture needle was developed. A small ureteral catheter or hardened polyethylene tubing is threaded through the needle into a branch of the portal vein as the needle is withdrawn, leaving the tubing in place in the vessel for future sampling. The tubing should be at least three times the length of the needle to allow the needle to be withdrawn over the tubing simultaneously with the feeding of the tubing into the needle to maintain the position of the tubing in the vessel. The unidirectional opening of the venipuncture needle facilitates the passage of the tubing into the vein without abutting on the vessel wall. Venography should precede and follow the withdrawal of the needle to confirm the location and direction of the tubing in the vessel. The polyethylene catheters have been left in place for 2 to 19 days without sequelae.

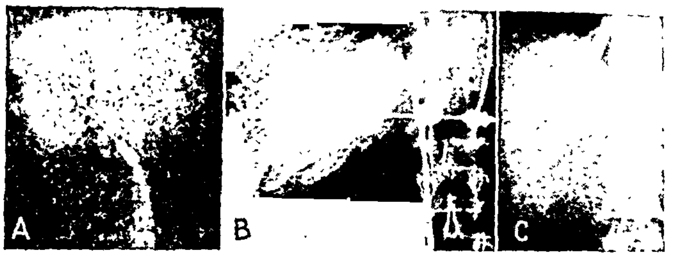

Fig. 2.—*A*, portal venogram with good filling of both lobes of liver. *B*, portal venogram of right lobe of liver. Catheter from below is in the inferior vena cava, with tip resting in hepatic vein. The catheter from above is in descending aorta, with the tip in hepatic artery. *C*, filling of hepatic vein by direct venipuncture.

For portal venography, 20 to 50 cc. of concentrated contrast medium is injected forcibly with the directional needle opening aimed retrograde toward the main portal vein. Sodium acetrizoate (Urokon) 70%, iodopyracet (Diodrast) 70%, or sodium iodomethamate (Neo-Iopax) 70%, have been employed satisfactorily and afford better contrast than can be obtained with 30% concentration. In this manner the major portion of the portal circulation may be demonstrated. Venograms via the needle afford more contrast than with the small-bore catheter or tubing.

RESULTS

One hundred forty-four transhepatic venipunctures were attempted in 73 patients. Portal venous blood was obtained in all but nine patients; in one patient with neurofibromatosis portal blood was not obtained despite five separate trials. Fourteen patients were catheterized via the portal or hepatic venipuncture needle, and the tubing was left in place for 2 to 19 days without sequelae. In three patients both the hepatic and the portal veins were catheterized by the transhepatic approach without untoward reaction. Portal venous blood clots so rapidly that heparin sodium in isotonic sodium chloride solution should be employed to maintain the patency of the needle or the catheter. The caliber of the polyethylene tubing is small, and it may require one to two minutes to obtain 3 to 5 cc. of blood. Drawing blood directly through a large-bore needle or tubing is recommended for rapid sampling.

Venograms were obtained in all patients to confirm the position of the needle or catheter. The vascular pattern of the portal vein as demonstrated by this technique was anatomically characteristic (fig. 2*A* and *B*). The splenic vein was also outlined when the contrast medium was rapidly introduced under pressure. In 13 instances the hepatic vein was visualized via direct venipuncture (fig. 2*C*). In three instances the inferior vena cava was similarly demonstrated. Hepatic arteriograms and portal venograms in the same patient on five occasions permitted accurate comparisons between the arterial and portal venous supply of the liver[4] (fig. 3*A* and *B*). Definite areas of tumor involvement were suggested by vascular distortion, and in many instances there were areas devoid of venous circulation that corresponded to metastatic nodules.

The hydrostatic pressure within the portal vein was estimated by the level of portal blood that rose in the needle and rarely exceeded 10 cm. above the right auricle in those patients without cirrhosis. In two patients with cirrhosis the portal venous pressure exceeded 20 cm. H_2O, and blood surged freely and spontaneously from the needle. Increases in intra-abdominal pressure (Valsalva's maneuver, vomiting) caused prompt and marked increases in portal venous pressure. Portal venograms in these two patients with cirrhosis showed a markedly constricted group of vessels limited to a small area of the liver[5] (fig. 3*C* and *D*).

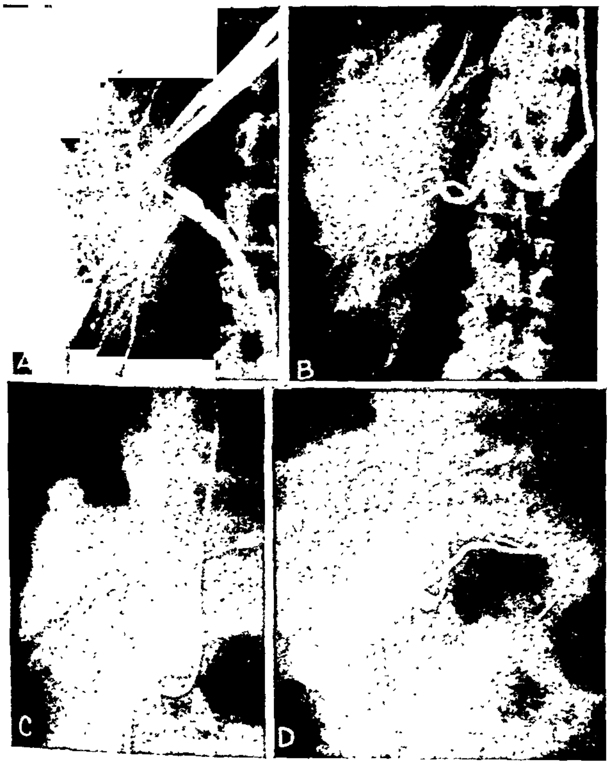

Fig. 3.—*A*, right superior branch of portal vein in a patient with Hodgkin's disease and hepatomegaly. Radiopaque catheter from above is in hepatic vein. *B*, hepatic arteriogram in same patient for comparison. Note relative decrease in arterial circulation, with areas of increased opacification. *C*, portal venogram with restricted visualization in patient with portal cirrhosis. *D*, hepatic arteriogram in same patient showing relative avascular pattern.

Blood from the portal vein was found to have a higher oxygen content than that obtained from the hepatic vein or the inferior cava and accordingly appeared more red than nonportal venous blood yet not as bright as arterial blood.[6] While the bright color suggested portal blood, it was not certain identification in all instances, as shown by venography. The glucose content of portal venous blood was determined after the oral ingestion of glucose. The increase in glucose content of the portal vein preceded and exceeded that in the arterial or venous blood from other sites. The bromsulphalein content of portal venous blood was found to be lower to a variable degree than that of the arterial blood. No significant differences were found in the portal venous content of protein, urea, sodium, potassium, chloride, calcium, or phosphorus when compared with blood simultaneously drawn from the hepatic vein, hepatic artery, or peripheral vessels. Occasionally marked differences were found in the leukocyte and platelet levels of the portal venous blood as compared with arterial or hepatic venous blood. The significance of these data remains unexplained.

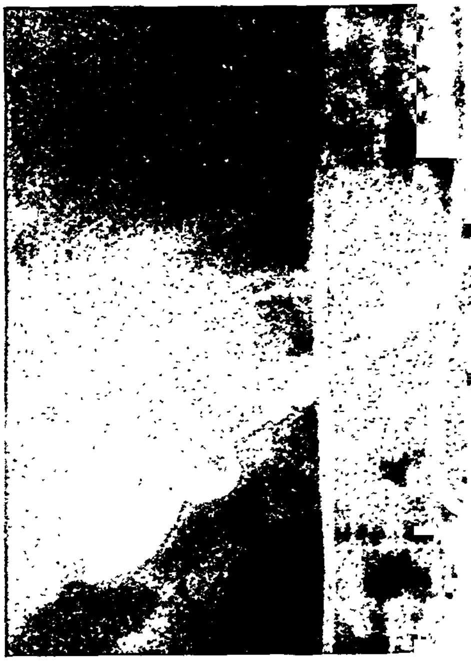

Fig. 4.—Direct transhepatic puncture of gallbladder demonstrating a persistent small defect in opacification presumably due to a stone.

Since many of the patients studied had widespread neoplastic diseases, it was possible to follow most of them until their death. Postmortem examinations were obtained in 55 of 62 patients (89%). Two patients were lost to follow-up. There were no serious complications attributable to the procedure. Several unexpected findings were encountered. Arterial blood was obtained in two patients, intestinal contents were aspirated in three patients, and in two patients concentrated bile was obtained. In one patient, the gallbladder was visualized by direct puncture, and a small defect, presumably a stone, was revealed (fig. 4). In the other patient, the cystic duct was entered and catheterized. In all instances the needle was withdrawn without sequelae. Evidence of bleeding after the venipuncture was found in three cases at postmortem; in one, a 2 cm. hematoma was found within the liver, and, in another, a 10 cm. hematoma was discovered on the surface of the liver. Death in neither case could be attributed to bleeding. In the third case, a 52-year-old man with advanced carcinoma of the lung with hepatic metastases and thrombocytopenia, 300 cc. of sanguineous ascitic fluid was found in the peritoneal cavity. Examination of the liver revealed the track of the needle had perforated through the undersurface of the liver at the anterior-inferior margin. Extravasation of iodopyracet into the liver parenchyma and beneath the capsule in the remaining patient was associated with transient syncope without sequelae. In some instances there was a small amount of extravasation of contrast material about the needle-end. This apparently caused no difficulty and was not visualized on repeat films taken 1 to 24 hours later. Portal venograms via the polyethylene tubing are difficult because of the small bore (fig. 5).

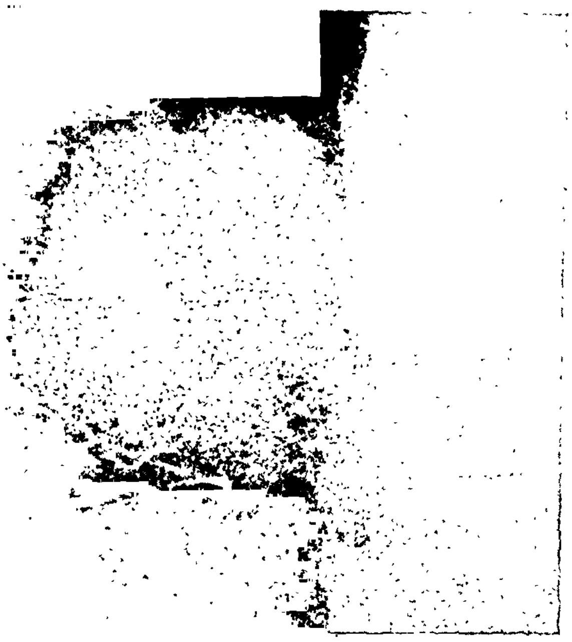

Fig. 5.—Visualization of a portal vein sampling site by radiopaque dye infusion via an indwelling polyethylene catheter. Catheter has been coiled over the abdominal wall for demonstrative purposes. Another polyethylene tubing has been placed in the hepatic vein with use of the transhepatic technique as for portal vein intubation.

COMMENT

The direct access to the portal vein by transcutaneous-hepatic puncture has permitted observations in man that have definite clinical value. The normal portal venous pressure fluctuates with the usual respiratory excursions, rarely exceeding 10 cm. Elevations in portal venous pressures up to 22 cm. H_2O were observed in patients with portal cirrhosis or intrahepatic portal obstruction and during Valsalva's maneuver or the act of vomiting. In the two patients in whom a branch of the hepatic artery was entered, the pressure coincided with the brachial artery pressure recorded by the cuff method. The measurement of the portal venous pressure by direct venipuncture appears to offer a simple and accurate method for determining portal hypertension and, together with a liver biopsy, may permit a more dynamic study of the alterations that occur in the development of portal cirrhosis. Although portal blood is usually a brighter red than peripheral or hepatic venous blood, a venogram is necessary to identify the site of the blood sample. In this manner the hepatic vein and inferior vena cava ca be excluded and catheterization or direct sampling fron the portal vein can be undertaken with assurance.

The venograms of the intrahepatic portal circulatio have demonstrated patterns that occur regularly unde specific conditions. The venogram in the noninvolve liver shows an orderly branching that closely resembl the normal anatomic configuration (fig. 2*A* and *B*). I the liver containing metastases, the large portal branche are sharply diverted around large areas devoid of venou vascularity and exhibiting many bizarre, nonuniform va cular patterns that are not seen in the normal liver. It ha been shown in many instances that hepatic metastases a generously supplied by the hepatic artery, far beyon anticipation.[4] It cannot be stated with certainty th hepatic metastases are not supplied by portal venou blood in all types of tumors. That there is relatively le venous circulation in and immediately about the met static area than occurs in the noninvolved areas, howeve appears to be demonstrable. The superimposition of va cular patterns at different levels throughout the liv tends to obscure many areas of small metastases appea ing in an area without venous circulation, particular since the films are exposed in a single plane, usual anteroposteriorly. Further elaboration of the relationsh of the venous blood supply of intrahepatic tumors w require meticulous comparison of the venograms with t injected specimens.

In the two cases of portal cirrhosis, the venogra showed an orderly but contracted vessel pattern restrict to a small area of the liver. Daniel and co-worker found a similar restricted venous circulation in rats wi cirrhosis.

SUMMARY

In 144 transhepatic portal venipunctures, perform in 73 seriously ill patients, no serious complications we encountered, although gastrointestinal contents were a pirated on three occasions and hepatic arterial blood w obtained twice. The portal circulation may be radiolog cally demonstrated by the injection of radiopaque med ums directly into the portal vein. For various studie serial samples may be obtained over prolonged periods l catheterization of the portal vein. The experience gain with this technique over the past two years indicates th portal venipuncture may be employed safely as a valuab clinical and investigative aid.

1500 E. Duarte Rd. (Dr. Bierman).

Hazard of Tinted Automobile Windshields.—Tinted optic media, particularly the darker brands of tinted windshield contribute significantly to the hazard in nightdriving, particular under conditions of low luminances and, consequently, sma visibility distances caused by poorly reflecting targets and bac grounds. Similarly dangerous reductions in visibility distanc were obtained . . . for twilight conditions, that is, when th driver has not yet turned on his headlamps. . . . Furthermor because of their relatively high transmittance, the effectivene of tinted windshields as a protection against glare during th day is negligible. Thus, their only advantage seems to be the ability to absorb radiant heat. . . . The best compromise appea to be the use of dark sunglasses for glare protection during th day, and clear windshields of the highest attainable transmi tance.—H. Haber, Safety Hazard of Tinted Automobile Wind shields at Night, *Journal of the Optical Society of Americ* June, 1955.

TOTAL REHABILITATION OF THE RHEUMATOID ARTHRITIC CRIPPLE

Edward W. Lowman, M.D., Philip R. Lee, M.D.
and
Howard A. Rusk, M.D., New York

Among the great numbers of severely disabled pers in our society, the plight of the person with chronic umatoid arthritis has been like that of no other. Beby a chronically progressive process, he has suffered n and crippling from a disease that has not had the rcy to kill but only the virulence to disable and wreck human body. Variously it has been estimated that to 25% of all patients developing rheumatoid arthritis l into this pattern of progressive disability and inidism.

Statistics concerning the extent of rheumatic disease the United States are at best inaccurate indexes. The vey reported by the United States Public Health Serv-[1] in 1938 is probably the most familiar; at that time was estimated that nearly 7 million persons in the ited States were suffering from some type of rheutic disease. More recently, in 1952, Woolsey [2] of the ited States Public Health Service reported results m a similar survey conducted among 25,000 houseds in 68 sample areas of 42 states. His findings製orated those of the earlier sampling. On the basis his sample group he estimated that in 1951 approxitely 10,104,000 persons beyond the age of 14 years, luding persons with rheumatic fever and rheumatic rt disease, indicated that they were afflicted with umatism. Of this group, 6,414,900 had had such a gnosis confirmed by their physicians. In addition, ause of their arthritis, approximately 2,500,000 had d to make some change in the type or amount of work t they had been carrying on.

The socioeconomic significance of this situation is dily apparent. With a disease of such magnitude possing a low potential for killing and a high potential disabling, it is not surprising to find that it leads all er diseases in crippling and in economic loss. In the ited States alone, more than 92 million man days per ar are lost because of rheumatism, with an annual nomic loss of 0.25 billion dollars.[3] In England rheutism accounts for 16.67% of all industrial disability d 6.25% of pensionable invalidism.[4]

Since these statistics are for rheumatic diseases in neral one can only interpolate in an effort to arrive some index for the incidence of rheumatoid arthritis. asmuch as 25 to 30% of patients routinely seen in a neral arthritis clinic have rheumatoid arthritis, one ight assume this to be a reasonable means for deducn. Regardless, the widespread incidence of rheumaid arthritis and of arthritic cripples is a well-established ct both in one's professional and often in one's private e.

PROBLEM

In the past, rehabilitation of the person with chronic rheumatoid arthritis was a tenuous undertaking so long as the disease process was an active and painful one; not only was the physical exertion inherent in rehabilitation poorly tolerated by the patient but the risk of accelerating the underlying process was a real one. By and large, therefore, rehabilitation was restricted to those chronic cripples in whom the disease process was quiescent or burned out.

Since the advent of cortisone, corticotropin, and other newer measures for controlling the inflammatory arthritic process, there has been an upsurge of hope and a resultant clamor among patients with chronic rheumatoid arthritis for a combined drug and rehabilitation program. The feasibility of this has been seriously questioned in many quarters, and relatively few patients have been accepted for such combined treatment programs. The major objection, it would seem, has been the dichotomous nature of adrenal oxysteroids in producing undesirable physiological effects aside from their desired anti-inflammatory effect; the more conservative regard for this two-edged situation that has developed among clinicians in the past four years and the consequent wariness under the circumstances for undertaking indefinite hormone therapy with such a patient are the factors that have been most decisive against such an approach. We have not been in agreement with this negative attitude.

In an effort to clarify the problem, we undertook an informal study three years ago of a pilot group of patients. These were all active, severely crippled persons with rheumatoid arthritis who were hospitalized and treated with a combined cortisone and rehabilitation program at Bellevue Hospital in New York. As a result of favorable impressions gained from treatment of this pilot group, a full-scale research project was initiated in December, 1951, at Goldwater Memorial Hospital to study the problem more thoroughly. The present report is based on findings of the first two years with this latter group of patients.

EVALUATION FOR REHABILITATION

Before proceeding it would be well to crystallize a mutual understanding of the connotation of the term rehabilitation. Rehabilitation has been described as the third phase of medicine, third, i. e., to (1) diagnosis and

(2) specific therapy. The *objective is the return of the* patient to his place in society, functioning within the limits of his disability but to the hilt of his capability. Such a concept entails an expanded responsibility of the physician to his patient that extends beyond the familiar first and second phases of medical responsibility. In most cases, rehabilitation, or the third phase of medicine, is assumed by the physician treating the patient for his specific illness and only in cases of severe disability are special rehabilitation facilities and special attention to job placement needed. Rehabilitation, however, under either circumstance cannot be divorced from diagnosis and specific therapy. On the contrary, its success depends upon a high degree of competence in these former. In the severe cases being reported here, special procedures have been necessary and have been prescribed and carried out under the direction of physiatrists as well as rheumatologists.

In the initial evaluation of a patient crippled with rheumatoid arthritis many kinds of information are needed before a reasonable program may be formulated.

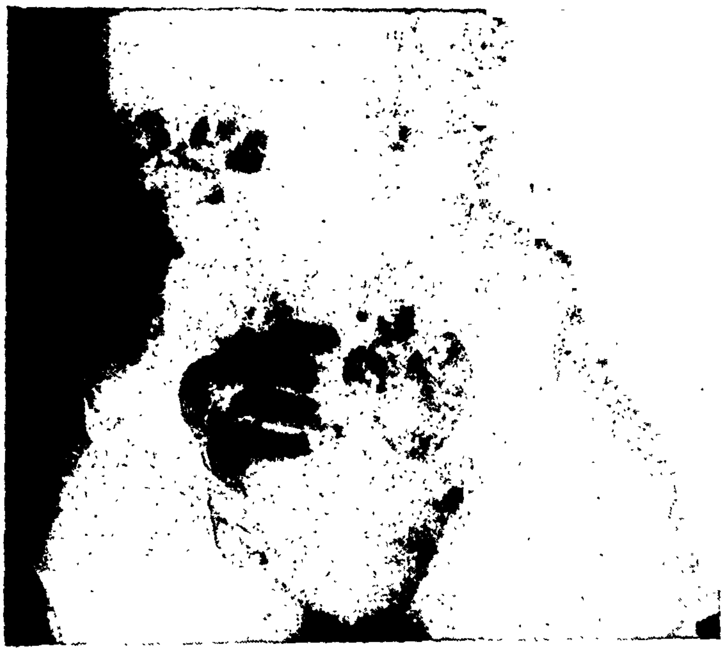

Fig. 1.—Damage in hip joints secondary to rheumatoid arthritis.

Medical Examination.—One must have first an accurate evaluation of the patient's arthritic process. This requires a detailed history and physical examination, laboratory examinations, roentgenologic examinations, and, where necessary, the consultative opinion of other specialists. From these data is derived some indication of the extent, severity, and "heat" of the arthritic process. It is of interest that of 285 patients referred to the project as severely crippled 24 or 9% did not have rheumatoid arthritis and 5% had rheumatoid arthritis but their disabilities were from causes other than the arthritis and of graver significance to them than their arthritis.

Functional Evaluation.—In addition to the above medical appraisal of the patient's disease, it is necessary to have other information that may pertinently modify the over-all prognosis and rehabilitation goal. First, the muscle status of the patient must be evaluated to identify weaknesses and the locations of these weaknesses. Individual muscles are tested and graded on a special chart originally developed and used for patients with poliomyelitis. This evaluation of muscle power is pertinent in the rheumatoid patient since joints are of no value to a patient if the muscles, which are the guy wires about the joints, are inadequate to stabilize and mechanize them. Next, joint ranges of motion are measured and recorded. This is important not only for determining total range of motion but also for establishing the phase of the range of motion arc in which ther may be limitation of motion. The latter is of considerabl greater significance from a functional standpoint tha the former. A knee, for example, may have excellen range of motion of greater than 90 degrees and still b contracted in flexion by a crucial 15 degrees, thus seri ously hampering the mechanics of weight-bearing.

The patient is then evaluated with actual functiona testing. While muscle power and joint ranges of motio are valuable sources of information and suggestive of functional capacity, the inference as to function is not always valid, for pain may be an additional limiting factor. Patients are therefore given additional tests in the performance of activities necessary to self-sufficient living. These many activities are collectively referred to as "activities of daily living" (table 1). This list of more than 100 activities ranges from the simplest bed and personal hygiene activities to the most demanding ambulation and elevation activities, including traveling via public transportation. The degree of functional impairment is thus directly measured and scored and, with the muscle power chart and range of motion measurements, correlation of functional with physical deficiencies can then be assessed. The sum total of these gives an indication not only of deficiencies but also of the physical potential of the patient.

Psychosocial Evaluation.—Finally, the psychological, the social, and the vocational assets and deficits of the patient must be appraised. What is the social and economic status? How has the patient psychologically adapted to the disease and what is his goal in rehabilitation? What intellectual and vocational assets are there upon which to formulate future plans? The minutiae of these facets are carefully sought out, for they may prove as acutely important to the over-all success of the rehabilitation undertaking as any of the more obvious medical aspects of the case.

The sum total of all these data—the medical, the functional, and the socioeconomic—is used collectively to establish a rehabilitation goal for a patient and to initiate treatment toward this end. Goals as established initially often are not static ones and may be changed repeatedly throughout the course of rehabilitation as dictated by unanticipated changes in the patient's progress. For the patient with severe arthritis, treatment programs usually must be full-day ones individually prescribed. They may include treatment sessions with various physical therapy modalities, occupational therapy, remedial exercise, functional training for deficiencies in activities of daily living, psychological and psychiatric assistance, vocational guidance, and, where necessary, job retraining.

METHOD

In the first two years of the study, 50 disabled patients with rheumatoid arthritis were accepted for treatment with a combination of drug and rehabilitation therapy. Initially in the first year of the study certain arbitrary criteria for admission of patients were rigidly adherred to. Patients had to be within the 21 to 55 year age group. The rheumatoid process had to be an active one. For purity of statistical analysis, patients obviously in need of corrective orthopedic procedures were excluded. There could be no medical contraindication for hormone therapy, and the patient had to have severe functional impairment. To quantitate functional incapacity more precisely than the class 1 through 4 system of the American Rheumatism Association, patients were tested and scored also in the performance of activities of daily living. This is a list of over 100 activities considered necesary to self-sufficient living. These were categorized into 10 major groups and to each group a score of 10% was ascribed. It was decided arbitrarily that a patient must score at least a 40% deficiency after establishment on cortisone or any other type of antirheumatic maintenance medication to be retained in the severe disability group. This group of the first year, consisting of 24 patients, is referred to as group 1.

In the second year of the study a more lenient set of criteria was adopted to obtain a comparison group. Patients still had to have an active disease process. Problems primarily of an orthopedic corrective nature were excluded. Functionally the patient had to be sufficiently disabled to be unable to carry on a gainful occupation, either a job in the case of the male or housework in the case of the female. Patients meeting these revised criteria are referred to as group 2.

In total, 24 patients meeting the initial criteria and 26 meeting the revised criteria were treated for periods of time varying from 7 to 21 months. All were hospitalized on the rehabilitation wards of the Goldwater Memorial Hospital during this study. After acceptance into this study patients were evaluated medically, functionally, and psychosocially along the lines outlined above. After evaluation, drug therapy was started; in most cases this was cortisone or hydrocortisone administered orally. When maintenance dosages of the drug were established, physical rehabilitation programs were then started and patients were continued on both drug and rehabilitation measures. As an index of improvement, scoring in proficiency in activities of daily living was done before any treatment, after maintenance antirheumatic drug therapy, and repeatedly throughout subsequent weeks or months of rehabilitation. In this way it was possible to measure increased function induced by drug and by combined drug and rehabilitation treatment for comparison and objective evaluation of treatments. After discharge from the hospital, patients have been followed at regular intervals as outpatients in a follow-up clinic.

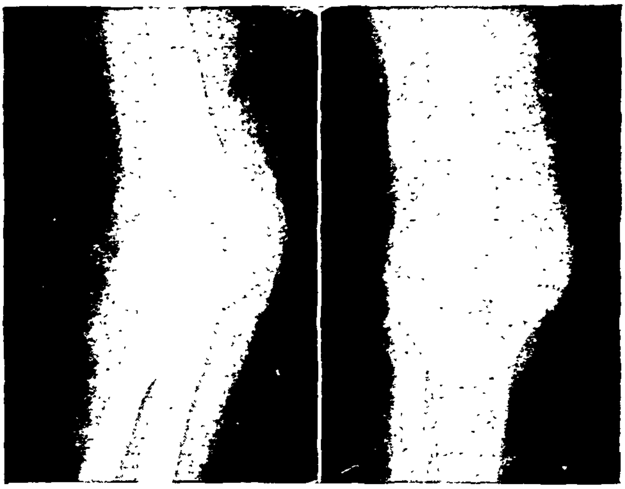

Fig. 2.—Damage in knee joint secondary to rheumatoid arthritis.

RESULTS

In the two year period of the study, 285 patients were referred to the project as "severely disabled rheumatoid arthritic patients" in need of a combined medical and rehabilitation program. For the reasons shown in table 1A 235 were rejected. It is significant that 24 of these, or 9%, did not have rheumatoid arthritis but suffered from other processes ranging from psychogenic rheumatism to metastatic prostatic malignancy. An additional 14 patients, or 5%, had rheumatoid arthritis but were more precariously disabled from other concurrent diseases. A total, therefore, of 50 patients was accepted for treatment. Of these, 24 were accepted the first year and met the rigid criteria for the severely disabled group (derelicts) mentioned above. In the second year 26 were accepted who were less severely disabled but still sufficiently disabled to be economically dependent. For various reasons 6 of each group were dropped from the study, leaving a total of 18 in group 1 and 20 in group 2 (table 2). It is of interest to note that of these 12, 3 were dropped because of frank psychosis, one because of borderline psychosis, and one because of hysteria; these clinical states were verified after the patients' admission to the hospital and precluded treatment with adrenal hormones. Three patients of the derelict group died during their hospitalization, one of cardiac failure, one of glomerulonephritis, and the third of an overwhelming septicemia; in no case were adrenal hormones contributory. For only one of the three had a rehabilitation program been started, and this had no relation to the fatal course of the preexisting disease process. The vital statistics of the two groups of patients are tabulated in table 2; it should be noted that the duration of the arthritis in the more severely disabled group was roughly double that of group 2.

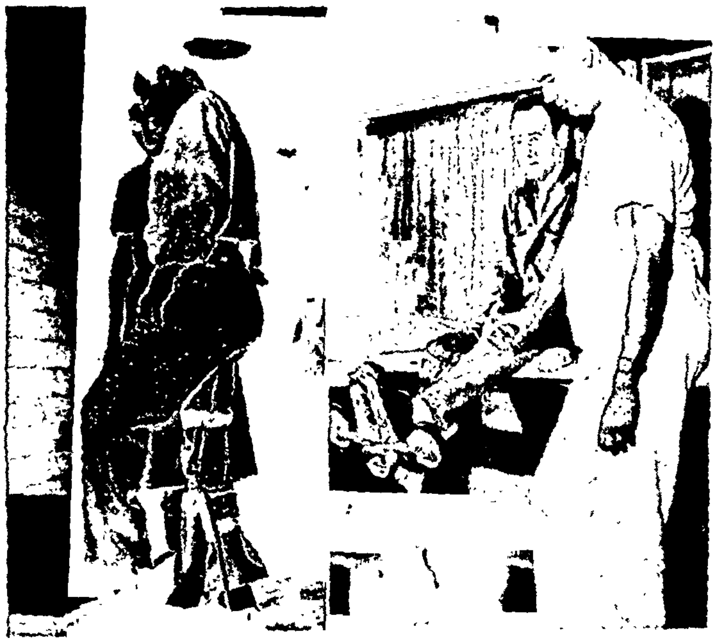

Fig. 3.—Patient doing progressive resistive exercise to build quadriceps power that will make elevation activities possible.

Since the ability of a patient with an active rheumatoid process to participate actively in an intensive rehabilitation program depends to a large extent upon the physician's ability to convert the progressive process into a static or partially static one, most patients required maintenance antirheumatic medication. Twenty-five of the 38 patients were treated with cortisone or hydrocortisone, while 8 were maintained on phenylbutazone. Only 5 of the 38 patients could be satisfactorily maintained on salicylates alone.

The results of treatment according to the American Rheumatism Association's method of classification showed that major improvements took place in the functional classes, with appreciable shifts from groups 3 and 4 to groups 1 and 2, indicating improvement in performance of activities essential to self-sufficient living. With use of the direct method of testing, the patient' ability to perform activities essential to daily living an his deficiency rating on a percentile basis are objectivel more apparent. This is shown in table 3. The average deficiency in group 1 was 60% initially, 53% afte establishment of maintenance antirheumatic medicatio and, finally, 29% after rehabilitation. Similarly, in grou 2, the initial disability average was 30%; after main nance medication this had decreased to 13%, and t final average after rehabilitation was 4%.

TABLE 1A.—*Reasons for Rejection of 235 Patients Referred to Project*

Reason	No.
Not rheumatoid arthritis	21
Disability not due to rheumatoid arthritis but has rheumatoid arthritis	14
Did not desire therapy on project	20

The final disposition of patients at the termination the initial two year period (table 4) left only four p tients hospitalized as custodial care cases; these were patients from the severely disabled or derelict group. would be expected the results were better with the le severely disabled than with those of the severely d abled group. However, 22 of the total 38 patients we totally self-sufficient upon discharge and 12 partial self-sufficient. Eight patients were placed in jobs outsi the home; this does not include those housewives w returned to their homes capable of resuming their jo as housewives, nor does it include patients engaged homework. In every patient, including the four remaining as hospital custodial cases, there was significant percentile improvement in function.

COMMENT

While it is still too early to arrive at final conclusions from this study, certain observations have crystallized that should be indicative of trends of thinking in this direction. As a result of our experience we have become acutely aware of certain key factors that seem to be of most decisive importance in determining the extent of the rehabilitation goal for a given rheumatoid patient. The positive or negative aspects of these factors seem to be the signposts that will most accurately indicate success or failure in attainment of objectives.

Drug Tolerance.—It is generally agreed that the ideal chronic rheumatoid cripple for rehabilitation is the patient with a burned out or quiescent case in whom control of the disease process has become an accomplished fact. Such patients present disabilities of a static nature, and the worrisome problem of a continuing disease process progressively worsening the disability is not a factor. We have included none of these in our study but have restricted the selection of patients to those with active disease processes. The control therefore of the active rheumatoid disease process has been necessary before undertaking rehabilitation. In our cases, the disease has been treated medically with various types of therapy but most frequently with cortisone or hydrocortisone. While we share the view with many others that the use of hormones generally should be restricted to a small portion of the over-all spectrum of patients with rheumatoid arthritis, the patients selected for this study all were of the group with chronic, active, progressively crippling disease processes that demanded any measure capable of partially or totally subduing the disease. In a large number of cases cortisone or hydrocortisone was the drug of choice. Our policy initially was to begin therapy with larger doses of the hormone and to gradually reduce dosage to a minimal maintenance level; in all cases, however, it was insisted that maintenance levels be below 75 mg. per day in the case of cortisone or 50 mg. in the case of hydrocortisone, even at the expense of permitting persistence of some of the disease symptoms. More recently the approach to maintain levels has been the reverse; steroid therapy has been started with small doses of 15 to 25 mg. per day and gradually increased to the lowest maintenance level capable of controlling symptoms, but again always restricting to the above maximum levels. We are more enthusiastic about this latter approach not only because of the lesser danger of undesired effects but also because patients accept a gradual build-up of dosage to a maintenance level more readily than the withdrawal of an excess. The initial therapeutic effect is a less spectacular one, but the over-all result is the same and attainment of it easier.

Group 2	20	....
Discharged totally self-sufficient	15	+21
Discharged partially self-sufficient	5	+29
Jobs	7	....

The effectiveness of the steroid in controlling the symptoms of the arthritis and the tolerance of the patient for the hormone are important factors modifying the attainment of rehabilitation objectives. One of us (E. W. L.) with Ward and co-workers [5] previously reported on the tolerance of patients for cortisone. At that time it was stated that if doses were maintained below 75 mg. per day the frequency of undesirable hyperadrenal effects was 21%, whereas if the dosage were kept at or above 75 mg. per day the frequency was three times as great, or 63%. In this present group of long-term patients we have seen hyperadrenal effects in 72%. In only two, however, was it necessary to discontinue the medication, and both were subsequently restarted on the same therapy. The length of treatment has ranged from 6 to 22 months. Only one patient has been maintained on a cortisone dosage above 62.5 mg. per day. Others have been maintained on a dosage ranging from 30 to 62.5 mg. per day.

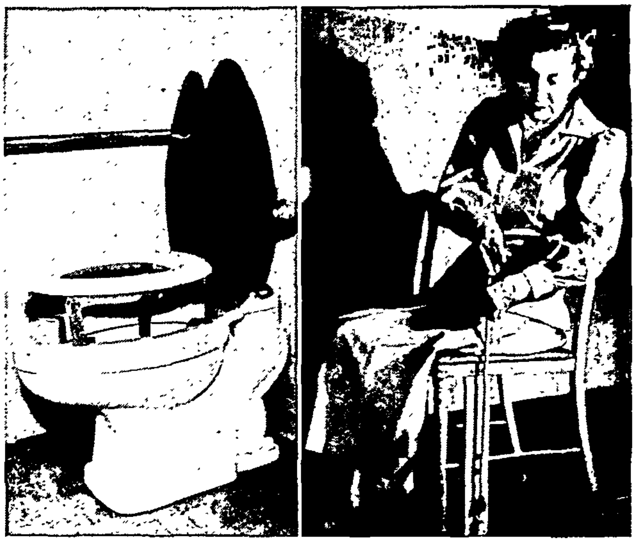

Fig. 4.—Elevated toilet seat to eliminate work from knees; chair elevated on casters provides mobility as well as additional height—standard doorstops have been adapted for locking it in a stationary position.

In six patients phenylbutazone has been an effective anti-inflammatory drug, and these patients have been satisfactorily maintained on this preparation. Two of us

[5] Ward, L. E., and others: Clinical Effects of Cortisone Administered Orally to Patients with Rheumatoid Arthritis, Proc. Staff Meet., Mayo Clin. 26: 361-370 (Sept. 26) 1951.

(E. W. L. and P. R. L.) with Brodie and co-workers have recently published extensive data on the use of phenylbutazone,[6] and on its analgesic and anti-inflammatory qualities and have particularly stressed its toxic implications.

In arriving at maintenance drug levels for the rheumatoid patient, one pitfall should be stressed. While the mechanisms of action of cortisone or of hydrocortisone remain to be clarified, it is established that their anti-inflammatory effect is the primary beneficial effect for the rheumatoid patient. It is important therefore that dosage be geared to this effect alone and not to pain. Since rheumatoid patients of the type reported here suffer pain from mechanical damage within joints in addition to the fibrositic pain of the primary disease process, steroid dosage should be regulated solely to cover the latter. When dosage is progressively increased in an attempt to alleviate the joint discomfort that follows use of mechanically impaired joints, the dosage frequently stepladders to much higher levels than would be necessary if the above criterion were adherred to. No attempt should be made to alleviate pain subsequent to hypertrophic changes but only that due to the rheumatoid process per se. Careful differentiation must be made clinically in evaluating these two sources of symptoms and the drug restricted accordingly if serious hyperadrenal pitfalls are to be avoided and long-term therapy carried out successfully.

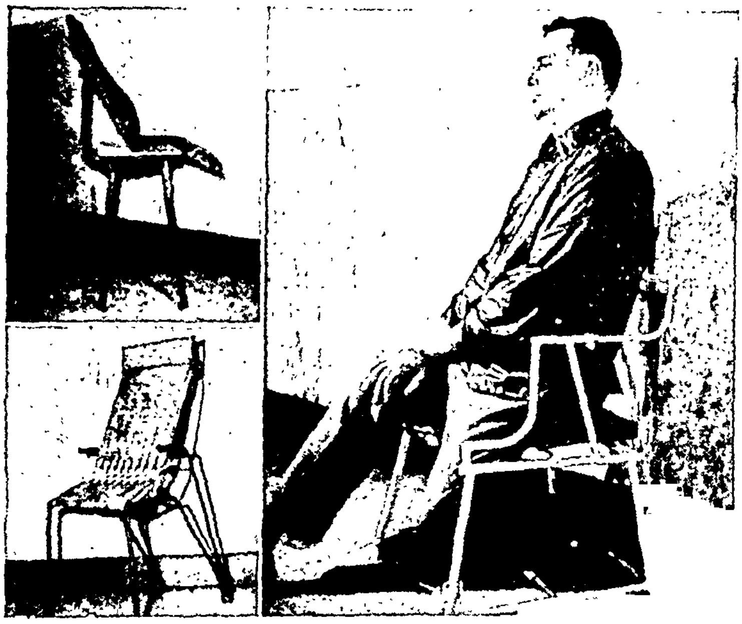

Fig. 5.—Right, chair, mobile on bearings, with cutout seat and knee rest to accommodate ankylosed hip. Upper left, high stool adaptable to sitting limitations of spondylitic. Lower left, chair with crutch tips to prevent sliding constructed with extra height and with adjustable sling seat to accommodate spondylitic.

Joint Mechanics.—The tolerance of joints for physical activity is dependent not only upon the degree of inflammation imposed by the rheumatoid process b also upon the extent of mechanical damage that has a crued. It must be remembered that, while the inflamm tory synovitis is the prominent presenting sign in rhe matoid arthritis, the disease process also produces chondritis, an osteitis, and a sterile osteomyelitis. All these predispose the joint to destructive changes in ca tilage and bone. Furthermore, such joints are intolera of normal amounts of work imposed by weight-beari and other normal activities and are more readily prone wear. These two factors, i. e., direct involvement by t disease process plus the tendency to wearing, predispo to destructive changes within the joint. These we pre to call secondary hypertrophic arthritis in contradisti tion to the inflammatory rheumatoid process (fig. 1 a 2). The degree to which secondary destructive chang have taken place will accordingly mechanically mod the tolerance of the joint for activity. These are ir versible changes, except for those that may be modif by orthopedic surgical procedures, and they impose li tations on a rehabilitation goal.

There is no ready index for determining joint tol ance. While roentgenograms are helpful, they may a be grossly misleading. We have come to rely upon th solely as confirmatory evidence. Frequently patients w roentgen evidence of severe damage will tolerate co siderably more strenuous exercise procedures than oth with minimal roentgen evidence of damage. Trial, the fore, is the best means of determining a patient's tol ance, and goals for a given patient must be modified conform to this tolerance of his joints. In the sever crippled group of patients seen by us it has not inf quently been clearly evident at the onset that ambulat was not a feasible objective, and treatment and train accordingly have been restricted to self-care, bed, a wheel-chair activities.

It should be pointed out that secondary hypertrop changes in joints of the lower extremities are much m restrictive than are such changes in upper extrem joints. This is as would be expected, since lower extre ities are primarily "work-horses" while upper extremit are mainly concerned with activities involving dexte and agility and are not weight-bearing. Goals in terms self-care and other self-sufficiency activities may aimed considerably higher in the face of upper extrem damage than in the face of lower extremity damage o comparable degree.

Psychological Soundness.—More so than with a other rehabilitation problem, the psychological timbre the rheumatoid arthritic is a major force in determini success or failure in attainment of goals. In the cou of this study we have become acutely aware of this fac and have intensively studied the problem with a ps chiatrist, a psychologist, and two psychiatric soc workers. The results of their observations have not in cated the existence of a predisposing rheumatoid p sonality as has been suggested by other investigato Rather, it is felt that in the course of a progressive d ease such as this, accompanied as it is by more and mo disability and a fluctuating but constant pain, the psyc becomes more or less inundated by the constancy, t hopelessness, and the helpless frustration to which it subjected. The result is an exhaustion of psychologic conomy and a reversion to passivity and dependency. t would appear that the degree to which the latter endency crystallizes depends not upon a preexisting pecific rheumatoid personality but rather upon the oundness of the patient psychologically prior to the onet of his arthritis and upon the tempo of the disease rocess. Since this process of regression to dependency a slowly cumulative one, it is unreasonable to expect hat sudden reversal of the state can be quickly effected. he reverse is true; the refractoriness of the deep seated ependency and passivity is the most restrictive factor in ccomplishing rehabilitation. It is easy to evaluate a paent medically and physically and know what goals are asible and within these limitations, but, unless a paent's goals are in accord with the physician's, the diverence in result will duplicate this difference in objective. n an effort to establish mutual goals we have undertaken o weld a good physician-patient relationship; this is articularly important with this group of patients who y and large have exhausted all medical resources without the relentless process of their disease having been halted; their alienation from physicians should be expected, and the reestablishment of confidence should be actively sought. In addition, we have utilized individual supportive psychotherapy and group psychotherapy sessions for airing and surfacing of hostilities.

O.: The Psychotherapy of Rheumatoid Arthritis, unpublished study.

Motivation of the patient is essential if rehabilitation goals are to be attained

Many patients with rheumatoid arthritis develop a passive dependency to their disease and to disability, which restricts rehabilitation possibilities

At times this dependency may be irreversible and it is wise to screen patients carefully from this standpoint before instituting a program

In the psychosocial survey of our patients the following factors frequently have been the indexes pointing toward motivation and possible success in rehabilitation

- Specific and realistic goals in rehabilitation
- Fair or reasonable standard of living
- Second generation American
- Good work history
- Successful marriage
- Moderate religious practice
- Financial independence at least five years prior to illness
- Minimal focus on hypochondriac symptoms
- Adequate ego strength
- Adequate body image

In the course of studying this almost inevitable passivity and dependence among these chronic cripples, we have found that in many patients it has been a reversible process that when approached therapeutically with the above measures would melt away and permit acceptance of reasonable goals. We have been interested, therefore, in trying to sort out the common denominators in these successful rehabilitees so that we might identify the assets they possessed that permitted them to carry on successful programs while others could not accept or work toward similar goals.[8] In analyzing psychosocial data in regard to the factors listed above, we have found that the typical successful candidate has been a second generation American of poor early socioeconomic status and moderate religious practice.

He has adjusted heterosexually in a normal fashion and achieved a successful marriage without evidence of conflict; where conflict arose he showed decisiveness in terminating the unsatisfactory marriage. He began work early without direct pressure and maintained a good work history. Economically he attained a fair or reasonable standard of living superior to that of his early family status and maintained his home independently with his spouse. Financially he had been independent for at least five years prior to the onset of his illness. The length of his illness was essentially the same as was the age of onset of his illness in comparison to the unsuccessful rehabilitee; his disability, however, was generally less severe. His attitude toward his illness generally was one of acceptance of life within limitations but with maximum function and without undue conflict. His goals in rehabilitation, in contrast to the vague, confused, unrealistic ones of the unsuccessful candidate, were generally specific and realistic. His use of the psychosocial department in the hospital was for control of the environment and for development of insight. In contrast to the unsuccessful candidate, his degree of focus on hypochondriac complaints was of only moderate or minimal degree. While he showed passivity and acceptance, it was with some conflict and considerable fear and reluctance to ask help from others; this was a sharp difference from the unsuccessful candidate, who was aggressive and demanding in his reaction to dependency. Psychologically, the successful candidate was of low-average or better verbal intelligence, with adequate ego strength; he showed control and limitation of both of his emotional experience and his imaginative experience, and his desire and capacity for pleasurable experiences far outweighed his depressive moods. There was rela-

[8] Lowman, E. W., and others: Psycho-Social Factors in Rehabilitation of the Chronic Rheumatoid Arthritic, Ann. Rheumat. Dis. 13: 312-316 (Dec.) 1954.

tively little oral need or concern with this and an adequate image of his body without distortion or bizarre interpretation. The unsuccessful candidate consistently showed the opposite of these psychosocial features to such an extent that we now feel the above to be good criteria for prognosticating which chronic arthritics may be good risks for acceptance into rehabilitation programs, and we have more recently undertaken to sift on this basis. These are the factors, we feel, that measure motivation in a patient.

Functional Training.—While joint ranges of motion, muscle power, and a joint's tolerance for activity are rough indexes of a patient's functional capacity, the latter is the primary objective and the former are important only as they contribute positively to function. Functional training in rehabilitation therefore is stressed and training is directed toward attainment of the maximum performance of those activities that are essential to independent daily living. The human body as a machine normally functions on a grossly inefficient level. It has been said that as human machines we are less 25% efficient. Even in the face of severe disabilities one may, therefore, be taught to attain a considerably higher degree of efficiency to compensate for irreversible physical deficiencies. Tedious training and months of practice may be required, but such an approach frequently provides keys to functional independence. Because of this, functional training is an important part of a patient's daily program and, as he accomplishes proficiency in one sphere, emphasis is then shifted to the next. Physical and occupational therapy treatments are directed toward strengthening of weak muscles and loosening of restricted joints, but only so that training in activities of daily living may be accomplished more readily (fig. 3).

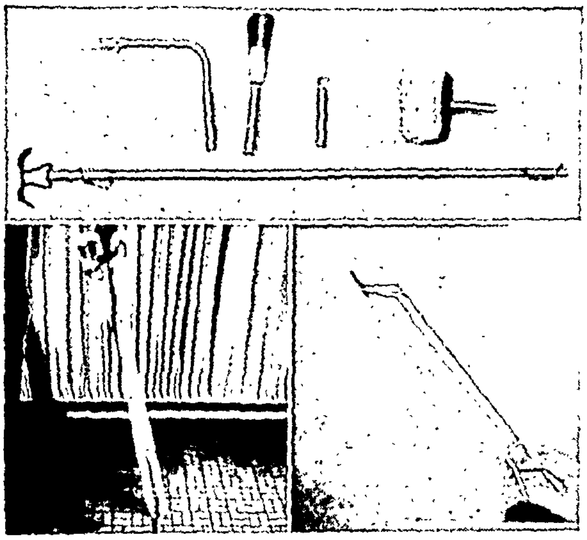

Fig. 7.—Top, all-purpose stick with attachments such as cellulose wash brush, hook, shoehorn, and comb for reaching inaccessible parts. Bottom, types of pick-up sticks useful for retrieving out-of-reach objects.

Socioeconomic Factors.—The reestablishment of the arthritic in a social and economic situation in which he may be able to function independently is, of course, the ultimate in rehabilitation objectives. The attainment of this goal either in part or in whole may require exhaustive resource and patience. The usual superficial social inquiry in itself is inadequate but must include detailed inquiry into the family structure and an intimate knowledge of the living conditions to be faced by the patien after his discharge from the structured and protective environment of the hospital. Apparent minutiae may assume crucial importance in determining the capacity o a patient to function in his home. The inability to clim three steps from street to house may make the differenc between ability and inability to travel to a job. A be or toilet or chair of satisfactory height or a bathroo door of sufficient width to permit entrance of a whee chair may be the factor determining whether a patien may live self-sufficiently alone at home or whether a attendant or a nursing home will be necessary. In mos cases the social worker must make one or several hom visits in an effort to clarify potential problems and t remove them. At times even relocation of housing ma be in order if this will enable the patient to travel to an from a job or if the change will render a patient sel sufficient in his new home, thus releasing another famil member to a job.

Job placement remains the most difficult objective t attain. There are few patients who could not carry o some gainful occupation were circumstances ideal an such resources as homework or sheltered worksho available to them. The most restrictive factor is inability to travel to and from work; most often this is a inability to utilize public transportation, but confinemen to home not infrequently results from isolation in walk-up apartment. The competitive labor market presents an additional obstacle to job placement. Sinc arthritics are physically unfit for manual labor and require specialized placement in relatively sedentary pos tions, the limited availability of the latter type job presents a problem unless the patient possesses precise skil or intellectual assets that may be sold. At times, re training may be indicated in order to accomplish th latter. If this is undertaken, the patient's psychologic and vocational aptitudes must be carefully assessed b the psychologist and vocational counselor in collaboration with the social worker so that formulation of re training plans may be on a practical level.

Special Devices.—Special apparatus is avoided unt its use becomes essential in order for the patient t function. When proficiency in an activity of daily livin requires additional mechanical assistance, only then ar special devices provided the patient. The great numbers of these self-help devices that have been develope for the arthritic are too numerous to mention except fo those more important ones notable for simplicity an usefulness.

Chairs, Wheel Chairs, and Toilet Seats: Chairs, (fig 4) wheel chairs, and toilet seats of standard height ofte pose major mechanical problems for the arthritic. Wit seats of a standard 17 or 18 in. height the work impose upon knees is frequently sufficiently painful to preclud use by patients who have involvement of these joints The sheering effect of rising from a standard height ca be eliminated by raising the seat of the wheel chair o chair structurally or with sponge rubber cushions to giv added elevation. Toilet seats, in like manner, may b mastered by the simple expedient of using a built-up removable seat that adds 4, 5, or 6 in. in height, or the toilet seat may be incorporated into a mobile chair that rolls over the toilet bowl. In instances of more disseminated involvement and especially in instances of rheumatoid spondylitis with peripheral joint involvement, it may be necessary to individualize the modifications to provide adequate sitting (fig. 5). This is especially true when there is ankylosis of one or of both hips in an extended position. Seats for such patients may be molded from Fiberglas impregnated with plastic and may be cut out or elevated as needed to accommodate the specific deformity.

Aids in Dressing: Dressing activities at times may be partially or totally impossible because of mechanical restrictions imposed by joint limitations. Zippered shoes, long-handled shoe horns, devices for putting on socks, stockings, and underwear, long-handled combs, and elastic shoelaces are often of advantage in these cases (fig. 6). An all-purpose utility stick with multiple attachments (fig. 7) has recently been developed for these purposes.

Aids in Feeding and Self-Care: In patients with shoulder or elbow limitations special long-handled devices for feeding and self-care (fig. 8) are helpful. Where hands and wrists are involved so that use of these joints functionally is impaired, special writing, feeding, shaving, toilet, and other devices offer assistance to the patient.

Crutches: Crutches, where needed, are usually an individual problem. This is apparent when one realizes the combinations of joint involvements that may present themselves in the upper extremities. Depending upon the residual function in the joints of the upper extremities, crutches must be worked out for the particular case. There are numerous variations of crutches, ranging from the standard hand-grip type to those permitting elbow resting.

Aids in Housekeeping: For the housewife careful planning and reliance upon such home energy-saving devices as work tables on casters and adjustable ironing boards can effectively reduce the work that otherwise might be placed on her joints in the course of her job as housekeeper.

Braces: Braces are infrequently used for the severely crippled arthritic. The notable exception is the patient whose lower extremity joints have been involved by destructive changes of a degree sufficient to cause pain on use. When knees or hips are so involved, bracing short of ischiatic weight-bearing is inadequate, and for such patients this type of brace is often prescribed with benefit; weight-bearing for such cases is thus shifted to the ischiatic tuberosity from the involved hip or knee. Splints are employed for two purposes: correction of deformity and prevention of deformity. The most important indication for correction of deformity is knee flexion deformity. In such cases a special type of knee extension brace is employed to maintain through the night the extension gained in the day by hot packing and manual stretching. In prophylaxis, two deformities especially are to be guarded against, i. e., wrist drop and ulnar deviation of the hand. For the former the old type of cock-up splint is still the most effective. Ulnar deviation on the other hand has presented a particularly perplexing problem. We have therefore experimented with many variations and have found that a Fiberglas molded splint is the most useful; this provides correction of the deviation and at the same time is light in weight and comfortable for the patient.

FOLLOW-UP STUDY

While the results of the first two years of this study have produced encouraging results for both the severely and the less severely disabled patient with rheumatoid arthritis, there still remain some doubts as to the general feasibility of the approach. The period of hospitalization required for these patients was protracted and costly in the face of such serious disability. If the patient, however, is permanently restored to self-sufficiency personally and/or economically, the investment can be justified, for in the long run it will repay itself in earnings either by the patient or by others in the home who may be released from caring for the patient to return to gainful occupation. The crux of the decision then, despite the initial favorable results, will remain to be answered in the follow-up study of these patients. Patients reported on in this two year study accordingly are now being followed as outpatients on a regular basis, and this follow-up will continue for a total of three more years. A number of questions yet to be answered will be solved in this observation period.

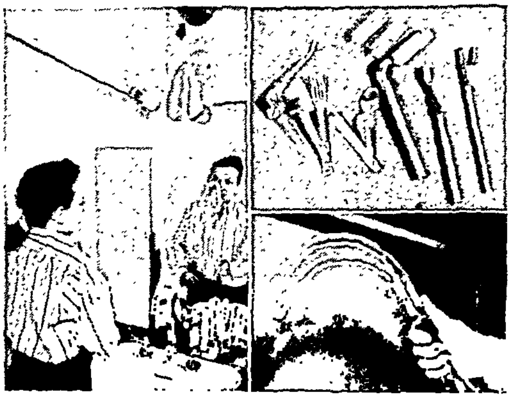

Fig. 8.—Left, wash cloth or powder puff holder. Upper right, long-handled utensils. Lower right, toilet paper holder.

Continued Control of the Rheumatoid Process.—Maintenance of functional gains will in large measure depend upon continued control of the inflammatory rheumatoid process. Patients therefore are committed to indefinite continuance of antirheumatic therapy. The length of time that administration of such medicaments may be continued without development of serious undesirable physiological or toxic effects is still a moot question.

Carry-Over into an Unprotected Environment.—The capacity of a patient to function within the protected environment of a hospital varies considerably from the nonstructured environment of home or job. The increased physical demands of the latter will undoubtedly impose added strain on the stability of the rheumatoid arthritis as well as greater mechanical stresses on joints. It remains to be seen whether continued use of functional gains will accentuate wearing (secondary osteoarthritis) within joints and result in regression.

Proper Housing.—The adequacy of housing has constituted a constant problem. In a metropolitan area such as New York City it is extremely difficult to locate low-cost living quarters with adequate space and without stairs. Low-cost housing projects are currently allocating a percentage of all new construction to disabled persons, and these quarters will be especially constructed to minimize physical hazards of living. Until these are available many patients will remain confined to walk-up flats either housebound or dependent upon others for assistance in getting in and out of apartments.

Continued Psychosocial Support.—Since the rheumatoid arthritic is frequently a more passive and dependent person, the continued availability of psychosocial support assumes significant importance. This will entail not only continued psychological support in the solution of vocational, social, and economic problems but also active assistance in working them out decisively.

Employment.—Placement of the arthritic in competitive employment is restricted by the stigma of crippling, by the mechanical impediment of assistive devices such as crutches, by the shrinking labor market, and by the restricted ability of an arthritic to use public transportation to and from work. Of all these factors, the latter is the most difficult hurdle in a city such as New York. Not only is traveling physically exhausting but also it imposes excessive work on joints that have little reserve; hence, it frequently is the insoluble obstacle to productive employment. Unfortunately, homework for housebound or semi-housebound persons or sheltered workshops for such persons are almost nonexistent. This s deplorable; of the patients who have undergone rehabilitation in this study, all but one could participate in homework or a sheltered shop with financial gain to themselves and with considerable resultant saving public assistance agencies at present rendering them nancial help.

SUMMARY

A total of 38 patients with chronic rheumatoid thritis hospitalized in the past two years were treat with a combination of medical and rehabilitation pr grams; 18 of these patients were severely disabled cri ples, and 20 were less severely crippled. The avera age of the severely disabled (derelict) group was years, with a disease duration of 13 years. In the l severely disabled group the average age was 40 yea with a disease duration of seven years. Of the 18 verely disabled persons, 14 have been discharged fr the hospital. Seven of these are totally self-sufficie and one has been placed in a job. The other seven ha been discharged partially self-sufficient, with an avera increase of 26% in functional capacity. Four patie of the group remain custodial hospital patients, among these there has been a 20% increase in functi Of the 20 less severely disabled persons, all have be discharged from the hospital. Fifteen are totally se sufficient, and the remaining are partially so, with average increase of 29% in function. Seven of these patients have been placed in full-time jobs.

With the concerted teamwork attack used in this stu it would seem that the patient with chronic rheumat arthritis does not have an insoluble problem and t many such people could be salvaged from their inval ism and brought back to the dignity of living. The tients engaged in this study are now being followed an additional three year period to verify the validity this inference.

400 E. 34th St. (16) (Dr. Lowman).

HYPOGAMMAGLOBULINEMIA ASSOCIATED WITH A SEVERE WOUND INFECTION

Earl O. Latimer, M.D., Edward J. Fitzsimons, Ph.D.
and
Paul S. Rhoads, M.D., Chicago

In recent years agammaglobulinemia, more properly called reduced gammaglobulinemia or hypogammaglobulinemia, has been reported in children.[1] This recently described entity is characterized by recurrent, severe bac-[illegible]al infections, which are evidence of deficient antibody [illegible]uction associated with almost complete absence of serum gamma globulin but with relatively normal total protein concentration. A patient with an abnormally low serum gamma globulin level, while under our care, veloped a severe surgical wound infection. We beli this patient's hypogammaglobulinemia either was sponsible for, or contributed to, her severe wound inf tion. To our knowledge no such condition has been ported as occurring in an adult; however, during t preparation of this paper, Sanford and his co-worker reported on an adult female, 39 years of age, who ha low serum gamma globulin level accompanied by bro chiectasis and a sprue-like syndrome. Their patient i proved markedly after administration of gamma glo ulin at monthly intervals. Subjective improvement w not apparent until 48 hours after the first injection gamma globulin. Janeway and his co-workers [1d] have r ported on a group of nine children with hypogammaglo ulinemia, six of their own patients and three the patien of colleagues. They report that several other patients whom deficiencies of gamma globulin have been tra

:nt, partial, or acquired in later life have been brought their attention. All clear-cut cases reported by Janeɪy and his co-workers [1d] have been in males. Their pants had no gamma globulin as determined by electrooretic analysis; however, immunochemical studies realed small amounts of gamma globulin (less than 30 ;. per 100 ml.). The continued administration of antiɔtics was only partially successful in preventing recurɪt infections: The injection of 100 mg. of pooled nor- :l human serum gamma globulin per kilogram of body ight once a month gave these patients striking protecn against infection. In the discussion of his paper, Git- [1b] stated that a total gamma globulin level of 100 to 0 mg. per 100 ml., obtained by injection of pooled man serum, appeared to prevent infection. Low gamma bulin levels associated with low total proteins and ma have been reported.[1c]

REPORT OF A CASE

A 39-year-old woman was admitted to Chicago Wesley :morial Hospital on June 1, 1953. She had been seen by one us (E. O. L.) in May, 1953, because of a mass in the right raclavicular area, known to have been present for five months. e patient's attention was directed to the mass because of slight n in her right shoulder and arm. It had not increased in size. had been seen by her family physician and a consultant, h of whom advised biopsy for diagnosis. The patient's parents re living, as were two sisters, one of whom had some allergies. ice after her pregnancies the patient's mother had had a ious infection, both of which "responded only to serum." Our ient had had measles, chickenpox, and mumps during childɔd, tonsillectomy and adenoidectomy at age of 6 years, and appendectomy in 1949. All convalescences were uneventful. 1950 she had an infected hematoma of the left thigh that was te resistant to treatment, but later an anal fissure was surally excised without postoperative difficulty.

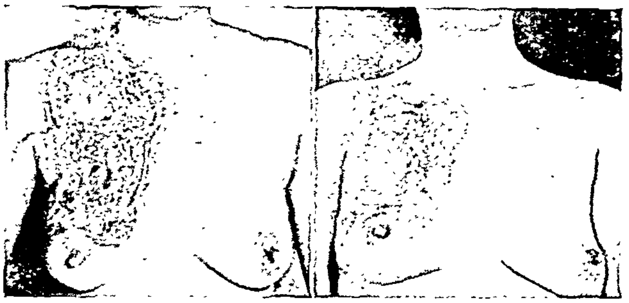
hysical and Laboratory Findings.—Upon examination on ıe 1, just below the right clavicle and lying deep to the pectoral scle, a movable, firm, and slightly tender mass, 5 cm. in greatest dimension, was found. Pressure on the mass caused n to radiate to the right shoulder. At 12 o'clock in the right ast was a 1.5 cm. nodule. Discrete, moderately firm, movable ɪph nodes were palpable in the right axilla. No enlarged ional nodes were found elsewhere. The remainder of the ysical examination gave essentially normal findings. Laboray findings preoperatively were hemoglobin 10.65 gm. per) ml. (68.5%), red blood cell count 4,050,000 per cubic millimeter, and white blood cell count 7,750 per cubic millimeter, h 70% polymorphonuclear leukocytes, 5% unsegmented lymorphonuclear leukocytes, 21% lymphocytes, 1% monoes, and 3% eosinophils. The results of the urine tests were thin normal limits. The prothrombin time was 80% of normal. e Kahn test was negative. The preoperative diagnosis was raclavicular and right axillary lymph node hyperplasia of un- :ermined etiology. The mass in the right breast was believed be a nodule of fat, but malignancy with metastasis to regional nph nodes was considered.

On June 2, 1953, the enlarged infraclavicular lymph nodes neath the pectoralis major muscle and the lesion of the breast re excised. The diagnosis following the tissue examination ıs follicular hyperplasia of lymph nodes and fibroadipose tissue ɔoma). The patient had a normal convalescence until her disarge from the hospital on the fourth postoperative day. At s time, a small amount of exudate escaped from the breast cision, but there was no evidence of cellulitis. Her temperature ıs normal. This was believed to be an insignificant wound inction, and the patient was permitted to go home. A moderate owth of Micrococcus (Staphylococcus) pyogenes var. aureus ıs cultured from the exudate.

Second Admission.—Two days later, on June 8, the patient ıs readmitted to the hospital because of a severe ıth surgical wounds. The wounds were opened ıick, creamy yellow-white exudate escaped. The

ture was 102 F, pulse rate 100 beats per minute, respirations 18 per minute, hemoglobin 10.3 gm. per 100 ml. (65.5%), red blood cell count 3,650,000 per cubic millimeter, and white blood cell count 10,650 per cubic millimeter, with 86% polymorphonuclear leukocytes and 14% lymphocytes. Fasting blood sugar level was 105 mg. per 100 ml. The liver profile was within normal limits. Penicillin was administered parenterally in adequate doses. The following day there was necrosis of the skin margins about the wounds. The skin and subcutaneous tissue at the edge of the wound became necrotic down to the muscle and overlying fascia. This necrosis continued to spread until the wounds coalesced and extended across the upper half of the right breast, the upper half of the right chest wall, and into the right side of the neck. At no time were the fascia and muscles involved, nor did the infraclavicular space beneath the pectoralis major muscle, from which the enlarged lymph nodes had been removed, become involved in the infection and necrosis. The oral temperature was 102.6 F on the third day, and the blood picture was hemoglobin 11 gm. per 100 ml. (71%), red blood cell count 3,960,000 per cubic millimeter, and white blood cell count 15,400 per cubic millimeter, with 94% polymorphonuclear leukocytes, 5% lymphocytes, and 1% eosinophils.

Repeated cultures of the exudate produced only a slowly growing nonhemolytic coagulase-negative M. pyogenes var. aureus organism. Anaerobic cultures were negative. Smears and cultures did not reveal a fungus. No streptococci or bacilli were found by smear or culture at any time. A micro-aerophilic nonhemolytic Streptococcus organism was repeatedly sought. No growth was obtained on blood cultures. Sulfonamides and various antibiotics were used in adequate dosage without apparent effect on the progress of the lesion. Antibiotics were used both systemically and locally. On June 8, therapy was begun with meth-dia-mer-sulfonamides (sulfadiazine, sulfamerazine, and sulfamethazine), 1 gm. every six hours; streptomycin and dihydrostreptomycin, 250 mg. each two times a day; aqueous penicillin, 300,000 units every three hours; oxytetracycline (Terramycin), 500 mg. every six hours; and erythromycin, 400 mg. every six hours. Therapy with the sulfonamides was continued for a total of 8 days, streptomycin, dihydrostreptomycin, and penicillin for 3 days, and oxytetracycline for 16 days. Erythromycin was given for 16 days, and then the dosage was lowered to 200 mg. every eight hours for 2 days.



Left, wound, June 19, 1953, showing extent of necrosis. Mark on right arm and axillary fold delineates upper and lateral extent of field receiving radiation therapy. *Right*, wound, Aug. 7, 1953. The wound is healed except for unepithelized central area. Complete epithelization had occurred by Oct. 7, 1953.

On the fifth day the total proteins were 5.42 gm. per 100 ml., with albumin 4.52 gm. per 100 ml., and globulin 0.9 gm. per 100 ml. One of us (P. S. R.) suggested that because of the low globulin fraction there might be a low gamma globulin, indicating that the patient was unable to build up antibodies against the infecting organism. Chemical and electrophoretic studies of the albumin and globulin content of the patient's serum were then made by one of us (E. J. F.), who also made comparative studies on the serum of the patient's father, mother, and two sisters (see table). Fresh whole blood as well as plasma was given, and efforts to secure gamma globulin were instituted. On June 13, 500 cc. of whole blood was administered and was followed by a chill and a temperature of 104 F. The next day, 250 cc. of reconstituted plasma was given, and the temperature again rose to 104 F. Reconstituted plasma, 500 cc., was given for the next three days, was skipped for one day, then was given again the next day, June 19. On July 3, after 500 cc. of whole blood was given, the patient had a chill. Gamma globulin could not be obtained immediately because, at this time, state regulations required that it be released only for protection against poliomyelitis.

On the 11th day x-ray therapy was started to the lateral portion of the wound only. In the meantime, the exposed pectoralis major muscle was becoming covered with healthy granulation tissue. The spread of the cellulitis process stopped on the entire periphery of the wound. On the 12th day bacitracin and reconstituted plasma were used locally. The following day, June 20, permission to use gamma globulin was obtained, and it was used locally in constant wet packs. Parenterally it was administered in the following intramuscular doses.

Date	Dose, Cc.	Date	Dose, Cc.
6/20	4	6/26	1.5
6/21	4	6/27	4
6/23	4	6/28	2
6/24	4	7/ 1	8

By the 17th day (June 24) of the second admission, the cellulitis at the periphery of the wound was rapidly subsiding. Healing progressed from the edges of the wound and from an occasional island of epithelium. Progress was rapid from this time on, and the patient was permitted to go home on the 30th hospital day. She was instructed as to arm exercises to avoid loss of function of the arm, and healing was complete on Oct. 7, 1953. Skin grafting was not used because of the fear of infection and necrosis developing at the donor site, even if split thickness grafts were taken. In December, 1953, the patient had an abscessed tooth. Gamma globulin and antibiotics were given prior to extraction of the tooth, and convalescence was uneventful. The patient has had no other serious illness or infection since.

COMMENT

The children reported by Bruton [3] and Janeway [1d] had very little resistance to infection, but the administration ooled gamma globulin gave them striking protection. their patients were males; our patient differs in respects, being an adult female who had normal tance to the usual childhood diseases. She has a definite hypogammaglobulinemia a ined by electrophoretic analysis and by an immu cal method.[4] This has persisted after her recov e serious cellulitis of the chest wall. There has ema.

The skin edges about the area o were dark, cyanotic, and undermined. The s sue had the appearance of a carbuncle. T isolated on multiple cultures of smear sections of necrotic tissue was a nonhemo negative M. pyogenes var. aureus sensitive biotics used, as shown in the following tab

Chloramphenicol (Chloromycetin)	10 mc.
Dihydrostreptomycin	60 mcg.
Penicillin	10 units
Polymyxin	5 mcg.
Oxytetracycline (Terramycin)	10 mcg.

This organism was absent from the cultures several days before the progress of the lesion was arrested; however, the local application of antibiotics could have been responsible for these sterile cultures. Although the process was arrested before pre a lobulin could be procured, the patient's recovery was rapid after she received gamma globulin. Prior to receiving this, she had received whole blood and plasma, which supplied some gamma globulin. There is no evidence to support the hypothesis that this was an allergic phenomenon.

Although the mother of our patient had two near fatal postpartum infections over 40 years ago and "was saved only by the injection of immune serum" (believed to be a polyvalent immune horse serum), at the present time her albumin-globulin ratio and gamma globulin level are normal. Those of the patient's father and sisters are also essentially normal (see table). The patient's low gamma globulin level has persisted up to the present (see table). Her recovery after the extraction of an abscessed tooth was uneventful; however, she received gamma globulin and antibiotics prophylactically prior to the tooth extraction.

It is our opinion that the hypogammaglobulinemia played an important part and probably was responsible for our patient's remarkably poor resistance to her infection. The causative organism by sensitivity tests had little resistance to all of the antibiotics available, and the

4. Gitlin, D.: Use uantitative Precipitin Rea

serum to 0.5 gm. per 100 ml. during the period of therapy with whole blood, plasma, and gamma globulin. It then returned to the patient's "normal" level of 0.3 gm. per 100 ml. The low albumin levels found electrophoretically during the illness apparently were an indication of the patient's poor nutritional state at that time; however, the amount of albumin present was always sufficient to prevent the occurrence of edema.

In January, 1954, three months after the patient's complete recovery, Dr. David Gitlin (Boston) determined the gamma globulin level in a sample of the patient's serum by his immunochemical method.[4] A value of 76 mg. per 100 ml. of serum was found, which Dr. Charles Janeway (Boston) states, in a personal communication, is "a very low level but considerably higher than the levels we have seen in children whom we feel have a congenital agammaglobulinemia." Janeway and others[1d] suggest that an absence of isohemagglutinins in the blood in patients of blood group O, A, or B may be used as a simple laboratory test on which to base a strong suspicion of the condition of agammaglobulinemia. Blood group B cells, suspended both in 30% bovine albumin and in isotonic sodium chloride, were used to test for the presence of antihemagglutinin (type B) in the patient's blood (type A); however, her serum was found to have a normal titer. Aside from a temporarily inverted albumin-globulin ratio, determined electrophoretically, which we ascribe to a poor nutritional state, the patient's liver profile was found to be essentially normal. Thus, this patient's hypogammaglobulinemia does not seem to be a reflection of faulty liver metabolism.

SUMMARY

The case of an adult female with a proved hypogammaglobulinemia and remarkably low resistance to a cellulitis caused by Micrococcus (Staphylococcus) pyogenes var. aureus is reported. The cellulitis did not respond to therapy until gamma globulin was added to the therapeutic attack. Since gamma globulin contains the immune bodies of the serum, more attention should be paid to this fraction in patients whose infections fail to respond to treatment.

ADDENDUM

On June 3, 1955, the patient's serum albumin-globulin ratio was determined by chemical analysis. Albumin was 5 gm. per 100 ml. and the globulin 1.5 gm. per 100 ml. Electrophoretic analysis of her serum revealed that a low gamma globulin level persisted. A modification of Kunkel's [5] zinc sulfate method for gamma globulin determination, which we now use as a screening test for hypogammaglobulinemia, revealed the presence of 0.2 gm. per 100 ml. (normal 0.8 to 1.2 gm. per 100 ml.).

THYROID HYPERPLASIA IN YOUNG CHILDREN

G. H. Klinck, M.D., Washington, D. C.

Thyroid enlargement in young children and infants has been seen in 10 cases received at the Armed Forces Institute of Pathology within the last two years. Cobaltous chloride and ferrous sulfate had been given in 5 of the 10 cases. Two recent communications, one by Gross, Kriss, and Spaet [1] and the other by Kriss, Carnes, and Gross,[2] described thyroid enlargement in a group of patients during the administration of cobaltous chloride for anemia and the regression of the goiter after the medication was discontinued. Even though the Armed Forces Institute of Pathology series is small, it seemed an appropriate one in which to compare the pathological changes in thyroids of children who had received cobalt with the changes in thyroids of others who had not received the drug. In the 10 children, enlargement of the thyroid was sometimes so marked that it interfered with breathing or caused death by suffocation. Five of the children were born prematurely. Lobectomy or tracheotomy was resorted to in some cases, and no attempt at surgical intervention was made in other cases in which death was due to suffocation.

From the Armed Forces Institute of Pathology.

The illustrations were supplied by the Armed Forces Institute of Pathology.

The one invariable pathological feature was marked, bilateral, uniform, and diffuse enlargement of the thyroid, which encircled the trachea. Microscopic examination revealed a striking similarity of altered thyroid architecture in all the cases. Hyperplasia was of such severity that a diagnosis of adenocarcinoma was considered by some examiners. Hyperplasia was found in all parts of the glands, and most of the follicles were obliterated. Rare round or oval follicles were present, but slit-like and sometimes branching spaces represented the few lumens that could be recognized. The cells lining the follicles were columnar, tall, and closely placed, and their bases appeared to rest on other cells rather than on a fibrous stroma. The slit-like follicles were almost always empty, but the periodic acid-Schiff reaction disclosed some rare intraluminal collections of homogeneous material considered to be colloid. In some cases the lumens were numerous and large, but almost always they were irregular in outline. Mitoses were not observed in most cases but were numerous in one. Subendothelial masses of hyperplastic thyroid cells were found in some cases. The subsidence of the thyroid swelling in the patients that lived and the absence of metastases in the autopsy cases dispel any idea of a malignant tumor.

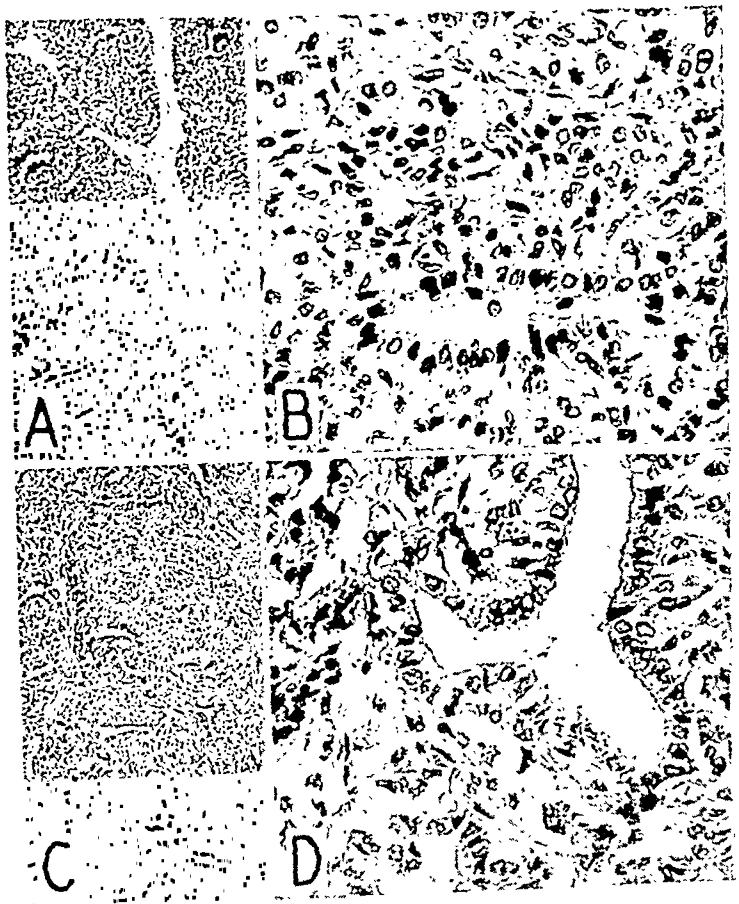

Fig. 1.—Photomicrographs of thyroid hyperplasia in premature infants who received cobaltous chloride: *A* and *B*, three and a half months and *C* and *D*, about three months. *A* and *C*, × 34.5. *B* and *D*, × 279.

Although all of the cases had similar pathological characteristics, it was surprising that five patients had received cobaltous chloride and ferrous sulfate and that five had not received this combination of drugs. The table shows pertinent data for these cases. Figure 1 shows photomicrographs of thyroid glands in cases in which cobalt was given. Figure 2 shows those in which the drug had not been used. On the basis of histological study of the thyroids it was not possible to differentiate between the patients who had and those who had not receiv cobalt. It should be pointed out that the same histologic picture of hyperplasia may result from many causes, a caution should be observed in ascribing the chang noted to any one etiological factor.

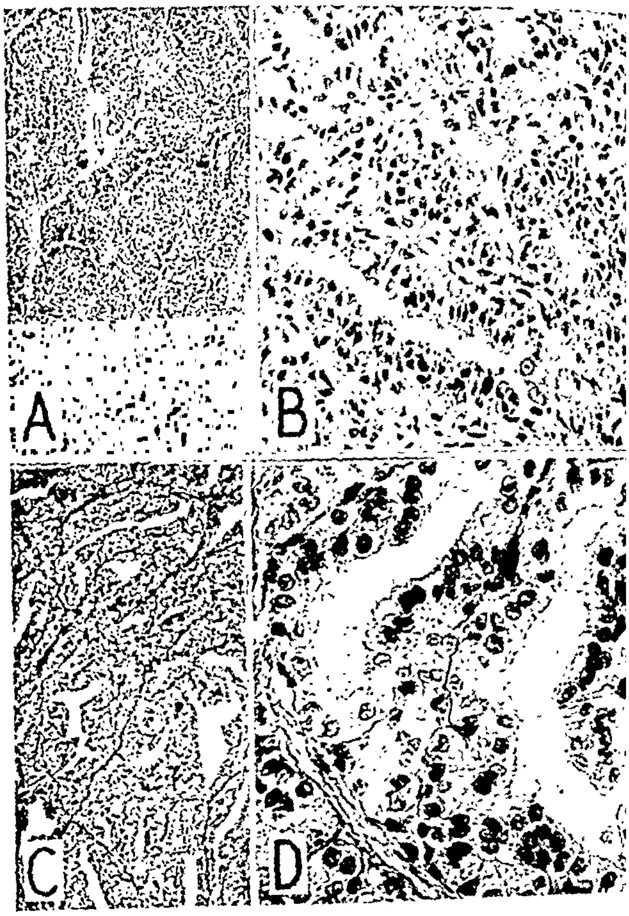

Fig. 2.—Photomicrographs of thyroid hyperplasia in infants who no cobalt. *A* and *B*, in a premature infant and *C* and *D*, in a infant. *A* and *C*, × 34.5. *B* and *D*, × 279.

SUMMARY AND CONCLUSIONS

In 10 cases of thyroid hyperplasia in childre children received cobaltous chloride and ferrous s On the basis of observations on a small num cases, the goitrogenic activity of cobalt cannot be lished. Further study of a larger series of cases i cated.

STUDIES ON IRON AND COBALT METABOLISM

Roy G. Holly, M.D., Omaha

Cobalt has been demonstrated to be effective in the tment of certain anemias.[1] In combination with iron, s of value in the treatment of anemia of prematurity l infancy.[2] Cobalt and iron have been found to be ctive in the prevention and treatment of most pregcy anemias.[3] In this article, it was stated that no toxic nifestations from cobalt therapy had been observed regnant women or their offspring. Because of current rest in cobalt toxicity, specifically, the possibility of alt inducing thyroid hyperplasia and hypothyroidism,[4] nplete investigations in animals and pregnant women to be reported.

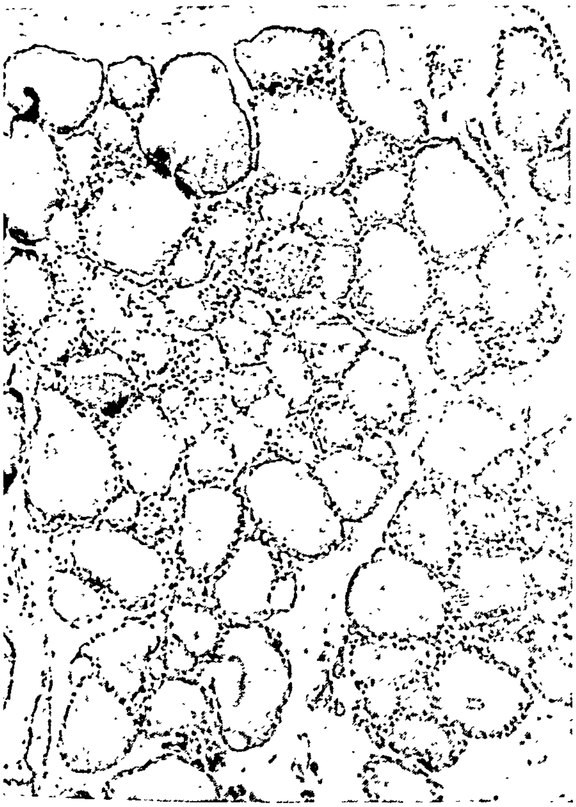

Fig. 1.—Photomicrograph showing normal rat thyroid (× 430).

METHOD

Observations on 78 pregnant women have been comted; 58 received cobalt and iron, and 20 received alt alone. The iron and cobalt preparation given to first group provided 60 to 90 mg. of cobaltous chloe with iron per day. The second group received 75 to 0 mg. of cobaltous chloride per day. Both groups reved the medication for a minimum of 90 days prior delivery. Some patients were treated for periods up to months. Hematological data on the patients receiving baltous chloride and iron have been reported.[3] Hemobin level, hematocrit, serum iron, and erythrocyte otoporphyrin determinations were done at four-week ervals during pregnancy and were repeated once in e puerperium. Tests for liver function included urine urobilinogen, feces urobilinogen, urine coproporphyrin, serum bilirubin, total lipids, thymol turbidity, and cephalin-cholesterol.

Twenty-six mature male white mice and 22 mature male rats bred from the Wistar strain were the subject of a separate investigation. Eight mice served as control (group M-1). Eight received propylthiouracil (group M-2), and 10 received cobaltous chloride (group M-3). The mice receiving propylthiouracil were given 0.2 mg. intraperitoneally daily for 10 days. The cobaltous chloride dose was 10 mg. per kilogram body weight given intraperitoneally daily for 10 days. As a test of thyroid function in the mouse, the closed vessel technique of Smith, Emmens, and Parkes [5] was used on the controls and treated groups.

Twenty-two male rats were divided into four groups. Three of the rats served as controls (group R-1); three received 10 mg. of cobaltous chloride per kilogram per day intraperitoneally for five and a half months (group R-2). Eight received 40 mg. of cobaltous chloride per kilogram per day orally for four months (group R-3), and eight received cobaltous chloride and ferrous sulfate equivalent to 40 mg. of cobaltous chloride and 200 mg.

TABLE 1.—*Summary of Animal Experiments*

of ferrous sulfate per kilogram per day orally for four months (group R-4). These data are summarized in table 1. At the completion of the experiment, the animals were killed. Tissue from the thyroid, pituitary, brain, salivary gland, heart, lung, kidney, liver, adrenal, spleen, stomach, pancreas, and intestines was fixed, embedded, sectioned, and stained with hematoxylin and eosin for histological examination. The hemoglobin level and erythrocyte count were determined on blood from the tail with the animal partially under ether anesthesia. Determinations were done initially and at two-week intervals during the study. Techniques for the hemoglobin level, erythrocyte count, serum iron, and erythrocyte protoporphyrin determinations have been reported. The liver function studies were done by the hospital laboratories, University of Minnesota Hospitals.

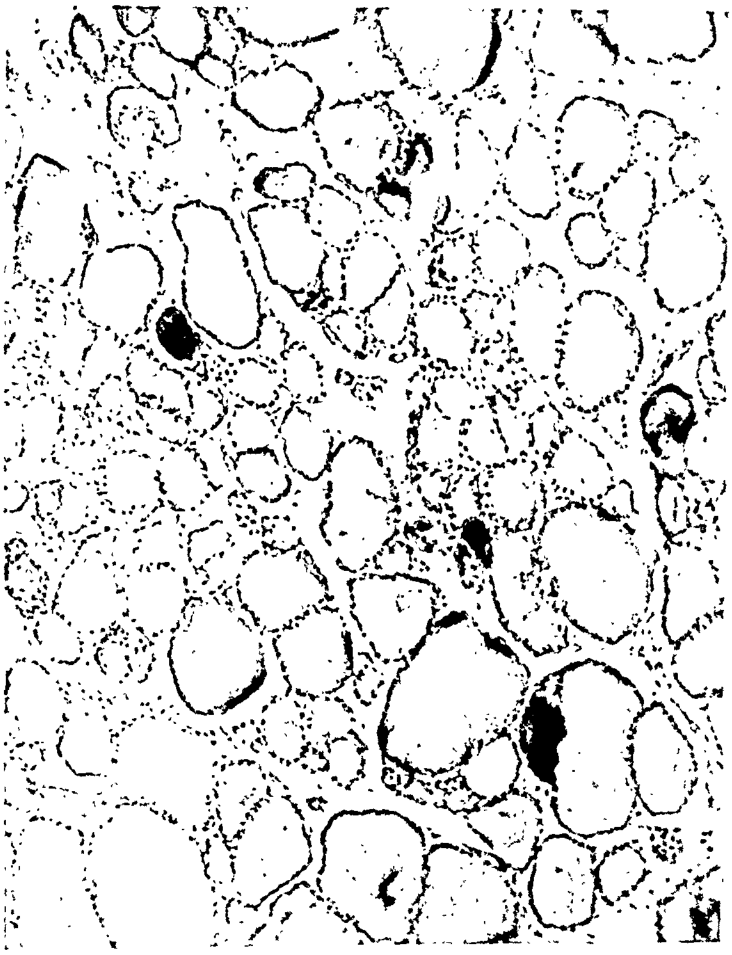

Fig. 2.—Photomicrograph showing thyroid from a rat that had received 10 mg. per kilogram per day of cobaltous chloride for five and a half months (× 430).

RESULTS

Hematological data on the patients and animals are shown in tables 2 and 3. In table 2, the blood findings from an additional 55 pregnant women who served as controls and 94 who received 1 gm. per day of an iron salt are included for comparison with those who were given cobalt alone or cobalt and iron. In those pregnant

women who served as controls, the reduction in hem
globin level and hematocrit was associated with a
crease in serum iron level and an increase in the eryth
cyte protoporphyrin. When the pregnant woman is giv
oral iron or iron and cobalt, the mean hemoglobin le
and hematocrit are maintained at or increased to
normal value. The serum iron level and erythrocyte pr
toporphyrin remain normal in the *majority* of pregn
women receiving iron or iron and cobalt. A comparis
of the control pregnancy group with those receiving i
or iron and cobalt emphasizes the need for supplemen
iron to prevent the exhaustion of maternal iron reserv

Cobaltous chloride without iron does not prevent
decrease in the hemoglobin level and hematocrit usua
found in pregnancy. As in the untreated group, the
crease in the hemoglobin level and hematocrit was as
ciated with a decrease in the mean serum iron level
an increase in the mean erythrocyte protoporphyrin
ues. *All of the women receiving* cobalt or cobalt and i
were judged to have normal pregnancies. Other tha
skin rash in one patient receiving cobalt and iron,
untoward symptoms from cobalt administration w
noted. No *thyroid* enlargement was noted in patients
ceiving cobalt. *Examination failed to disclose thyr*
enlargement in any of the *children born to mothers*
ceiving cobalt or cobalt and iron during pregnancy. Li
function studies were carried out on 11 of the won
receiving cobaltous chloride. Aside from the elevatior
the urine urobilinogen in four patients, the remainde
the results were within normal limits. The liver funct
studies on pregnant patients receiving cobaltous chlor
are shown in table 4.

The unique property of cobalt to stimulate eryth
poiesis is shown in the animal experiments (*table*

COMMENT

The mechanism by which cobalt exerts its effect on ie hematopoietic system is not known. Hypotheses that obalt acts by direct anoxia of the bone marrow cells [8] r by an indirect tissue anoxia due to enzyme inhibition [1a] ave been convincingly discredited.[9] Cobalt is absorbed om the intestine and is excreted primarily by the kidney ıd to some extent in the bile. No serum cobalt level has er been demonstrated, except in individuals receiving balt. Human erythrocytes produced by cobalt stimula- on are normal in appearance and have been shown to ave a normal survival time when transfused into recip- nts.[10] Cobalt is therapeutically effective in many ane- ias; particularly those associated with hypoplastic or plastic bone marrow changes. Cobalt with iron has een shown to be effective in the treatment of the most equently seen anemia in pregnancy and in anemias of rematurity and infancy.[2] We have routinely adminis- red cobalt and iron in a clinic obstetric practice. Un- oubtedly, there is widespread usage over the country. he common anemia in pregnancy results from a defi- ency of iron. By administration of an iron salt, hemato- gical decreases in about 80% of pregnant patients can e prevented. The significant effect of cobalt combined ith iron is the maintenance of normal hematological alues in nearly 100% of the patients. Predelivery hemo- lobin level values of 13 to 14 gm. per 100 cc. occurred ore often in pregnant women receiving iron and cobalt han in those receiving an iron preparation alone. Cobalt as been found to be effective in the treatment of hypo- lastic anemia of pregnancy.

Any substance of value in the treatment of disease nust necessarily be considered in the light of possible oxic effects. In spite of widespread use of cobalt and iron, o serious toxic manifestation has been reported, except hat observed by Kriss, Carnes, and Gross.[4] Minimal astrointestinal symptoms may occur in a small percent- ge of patients. An occasional patient may develop a skin ash, which promptly disappears when cobalt medication s discontinued. An excess of a heavy metal may result n liver damage. It is logical to study this organ for pos- ible cobalt toxicity. The battery of liver function studies on patients under cobalt therapy during pregnancy indicated that cobalt had no deleterious effect upon the liver. There is no way to interpret the elevated urine urobilinogen excretion values determined on four of the pregnant women, since pretreatment values were not obtained. Other equally sensitive tests were negative. The urobilinogen values outside the normal range probably were not significant. Rats maintained on an intraperitoneal dose of cobalt equivalent to 100 to 160 times a dose normally used in human therapy were found to have no abnormalities in their liver architecture. Hopps, Stanley, and Shideler arrived at a similar conclusion in their histopathological studies of rats receiving cobaltous chloride.[12] It is safe to assume on the basis of these animal experiments and the experience in human beings that cobalt does not produce liver disease.

Kriss, Carnes, and Gross [4] recently reported the occurrence of thyroid enlargement, thyroid hyperplasia, and hypothyroidism in children receiving cobalt. Thyroid function studies by means of radioactive iodine (I^{131}) uptake, protein bound iodine, and cholesterol determinations were a part of this report. Thyroid symptoms and laboratory findings returned to normal when cobalt was discontinued. Scattered references to similar thyroid enlargement attributed to cobalt administration have crept into the literature in recent months. Aside from one instance in the Kriss report, all examples of thyroid disturbance have occurred in children. The case of one adult, cited by Kriss, was that of a 55-year-old woman who died of myocardial infarction as a sequela to severe renal disease and hypertension. This woman had nitrogenous retention and had received hexamethonium. It seems unfair to implicate cobalt as solely responsible for the abnormal thyroid pattern observed at autopsy on this woman. Extensive investigations on animals and children have failed to confirm the findings reported by Kriss and others. Scott [13] has administered cobalt and cobalt and iron to rats in a dose sufficiently large to produce polycythemia. He concluded that cobalt had no effect on iodine metabolism. Thyroid I^{131} uptakes were normal in rats after prolonged cobalt administration. The I^{131}-bound hormone was normal in all phases of his investigation, indicating that the thyroid was trapping iodine, synthesizing thyroxin, and releasing it into the blood stream. The distribution of I^{131} was normal in all tissues.

Jaimet and Thode[14] have been unable to demonstrate any thyroid enlargement or significant alteration of thyroid function in children after 9 or 10 weeks of cobalt administration. They varied the cobalt dosage to provide 1 to 6 mg. of cobaltous chloride per kilogram per day. The iodine uptake, conversion ratio, and saliva protein-bound iodine activity ratio were not affected by cobalt administration in these children. The children receiving 6 mg. per kilogram per day were receiving twice the amount of cobalt given by Kriss to the one control patient in whom thyroid enlargement was produced. Only the I^{131} uptake was reduced during the period of cobalt administration. The paradox of normal cholesterol and protein bound iodine values, associated with decreased radioactive iodine uptake, was observed in one other patient. The conclusion that cobalt produces thyroid hyperplasia and hypothyroidism scarcely seems justified on the basis of the Kriss investigation.

* Rats were maintained on Purina Laboratory Chow. This diet contained 326 ppm of iron and presumably supplied adequate iron for hemoglobin synthesis in these experiments.

The animal investigations reported here, with those of Scott, would indicate that cobalt does not alter thyroid metabolism in the rat. While animal experiments cannot always be used as a basis for judging pharmacological action in the human being, it is generally recognized that the rat and mouse thyroid glands are more susceptible to goitrogenic agents than the human thyroid. Observations on pregnant women and the more detailed investigations on children receiving cobalt and iron would substanti the absence of any goitrogenic action on the part of cob Cobalt and cobalt and iron have been administered thousands of children and adults in the prevention treatment of anemia in the past decade. Probably more than a dozen examples of thyroid enlargement h been recorded. The coincident occurrence of thyr enlargement, with or without disturbance of thyroid fu tion, with cobalt administration could be explained m reasonably on the basis of a chance relationship, ra than any goitrogenic action of cobalt.

SUMMARY AND CONCLUSIONS

In an investigation on animals and pregnant wom a group of 55 normal pregnant women served as a trol. In this group, there was a decrease in the m hemoglobin level and hematocrit associated with a crease in the mean serum iron level and an increas the mean erythrocyte protoporphyrin. A second g of 94 pregnant women was given an iron suppleme their diet. A third group of 58 pregnant women rece an iron and cobalt preparation. A supplement of iro iron and cobalt effectively prevented any reduction i mean hemoglobin level and hematocrit during pregn A fourth group of 20 pregnant women received onl baltous chloride, which did not prevent a decrea hemoglobin level and hematocrit.

THYROID FUNCTION STUDIES ON CHILDREN RECEIVING COBALT THERAPY

Charles H. Jaimet, M.D.
and
Henry G. Thode, Ph.D., Hamilton, Ontario, Canada

Gross, Kriss, and Spaet,[1] in 1954, reported that thy- oid hyperplasia and goiter had developed in several ildren receiving an experimental cobaltous chloride reparation. Details of what appear to be the same cases ave more recently been reported by Kriss and co- orkers.[2] Although premedication values were deter- ined in only a single case, thyroid function studies led em to conclude that suppression of thyroid function ue to cobalt was the primary cause of hyperplasia and onsequent goiter formation. Also, biochemical studies f Kirkwood and Fawcett [3] in this university indicate at the activity of the thyroid enzyme tyrosine iodinase inhibited in a cell-free thyroid homogenate by cobalt 10^{-6} M concentrations.

Antithyroid agents generally are effective in animals,[4] d their potency can usually be established promptly the effect of single doses on the thyroid function test human beings.[5] However, Kriss [2] and others [6] report at cobalt meets neither of these criteria. Previous work ported from our laboratories [7] has dealt with the iodine ycle in human beings and with the use of saliva protein- ound iodine activity ratios as a sensitive, reliable indi- ator of thyroid function and of the hypothyroid state in articular. Because of our interest in this field, as well as the use of cobalt-iron therapy in anemia, we thought it esirable to investigate further the antithyroid effect as- ribed to cobalt by Kriss and co-workers.[2]

† Five weeks with therapy; 5 weeks without; last 4 weeks with therapy.
‡ Pretherapy I^{131} tests were for some unknown reason above normal. The subsequent post-therapy normal levels do not, therefore, justify any nclusion one way or the other regarding effect of cobalt, and tests on this patient were discontinued.

METHODS AND MATERIALS

Preliminary thyroid function studies and careful clin- cal examinations were carried out on a group of 18 chil- lren, aged 5 to 9. Ten were male, and eight were female. Details of the radioactive iodine uptake, conversion atio, and saliva protein-bound iodine activity ratio echniques used have been reported.[8] The inclusion of he latter procedure seemed especially desirable since we have shown it to be relatively more accurate in de- tecting the hypothyroid state.[7a] The tracer dose of 50 μc of radioactive iodine (I^{131}) was administered to all of the children on the same evening. Iodine uptake studies were made with Geiger and scintillation counters 24 hours later, and blood and saliva samples were taken for the other determinations. It was felt that the uniformity of the group procedure might eliminate possible causes of variation in the test results.

On the day following the preliminary function tests, medication with a liquid cobalt-iron preparation was begun. Dosage was so adjusted that four of the children received 1 mg. of cobaltous chloride per kilogram of body weight per day, five received 2 mg. per kilogram, four received 4 mg. per kilogram, and five received 6 mg. per kilogram. The treatment was given once, twice, three times, and four times a day respectively. These doses were chosen because they are representative of the range of dosage that might be expected when the commercial product is used according to the directions supplied and because the dosage reported by Kriss and co-workers [2] in their single "controlled case" was at the median of our dosage range. Furthermore, the maximum dose used by us has previously been indicated to be safe for use in children.[9]

Five weeks and again 10 weeks after therapy was begun, the battery of function tests was performed as described above with the same precautions as to group procedure. One patient (case 18) was dropped from the study because pretherapy I^{131} tests were, for some unknown reason, above normal. The subsequent post-therapy normal levels do not therefore justify any conclusions one way or the other regarding effect of cobalt.

From Hamilton College, McMaster University.

The cobalt-iron preparation used in this study was supplied as Roncovite drops by Lloyd Brothers, Inc., Cincinnati.

S. Nablo, Alex Harrison, Harold Amy, and Mary Evel gave technical assistance.

After the five-week period, therapy was discontinued in two of the patients receiving the 6 mg. per kilogram dosage. These two patients (cases 16 and 17), whose tests are shown separately in table 1, showed a sharp depression of thyroid function according to the I^{131} studies. They did not then nor subsequently exhibit any goiter or any signs or symptoms of hypothyroidism. They were, and are, in fact healthy and asymptomatic. After due consideration it was decided to discontinue cobalt therapy, repeat I^{131} tests in another month, and then, if tests were normal again (as they were), reinstitute cobalt therapy for another four-week period. Final assessment showed no added fall in thyroid function. We do not offer any suggestion as to why these two children showed this reaction, but obviously cobalt was not suppressing on the second course, and, if anything, they were handling iodine and making thyroxin better at the last than before cobalt therapy. The administration of cobalt therefore covered a period of 10 weeks in all patients. During this time, the children lived together in an institution under similar living conditions, with similar diet and with administration of the medicament supervised by an attending nurse. This eliminated the possibility of irregular administration. Frequent clinical examinations were carried out with particular attention to the thyroid gland, and no change in their healthy state was observed. Hemoglobin level determinations were done by standard methods, samples being taken at the time the thyroid function studies were done.

RESULTS

Results of all three thyroid function studies are shown in tables 1 and 2. In none of the children was there any approach toward hypothyroidism, and even casual inspection shows the lack of significant variation over this extended period. It would appear that cobalt was completely without effect on thyroid function in these cases. In no instance were gastrointestinal side-effects seen from the medication. No clinical signs of hypothyroidism were seen at any time, nor was there any clinical evidence of thyroid enlargement at any time in any patient. In fact, the children and their supervisors all remarked on their sense of well-being throughout therapy. Hemoglobin level findings are shown in table 3. Since iron deficiency may be assumed to have been present in several of the patients, the increases that appear are those to have been expected. No conclusions, of course, could be drawn from this work as to the relative merit of cobalt-iron and cobalt alone. The figures are included, however, because Kriss [2] had reported a sharp fall in hemoglobin level values coincidental with goiter formation in patients receiving cobalt.

COMMENT

In the single case of sickle cell anemia reported by Kriss and co-workers,[2] in which thyroid function studies were done prior to and during therapy with cobaltous chloride, a very pronounced fall in iodine uptake to 2% was reported after nine weeks of therapy at a dosage of 3 mg. of cobaltous chloride per kilogram per day. A goiter designated as 2+ was reported to have de-

veloped. Since these authors were able to demonstrate this result in a case selected at random, it would be unlikely that it presented a coincidental idiosyncrasy. In our series of 17 cases, we could find neither such change in function nor development of goiter. We therefore could not confirm the findings of Kriss and co-workers [2] in any way, even at dosage levels twice as great as used by them. Several explanations appear to be possible. First, none of our patients had sickle cell anemia, whereas Kriss and co-workers [2] drew their conclusions concerning hypothyroidism solely from children with this disease. However, other studies [10] with cobalt in patients with sickle cell anemia have likewise failed to confirm their results. Since cobaltous chloride is not an official drug, specifications for medicinal quality are not available, and it is possible, of course, that variations in the quality of the drug could be responsible for the findings of Kriss. The presence of toxic impurities in some samples of commercially available cobaltous chloride have been reported.[11]

SUMMARY AND CONCLUSIONS

The administration of a cobalt-iron preparation in a dosage providing 1, 2, 4, and 6 mg. of cobaltous chloride per kilogram of body weight daily for 10 weeks caused no significant change in thyroid function in 17 children. Function studies included radioactive iodine uptake, conversion ratio, and saliva protein-bound iodine activity ratio determinations. No thyroid enlargement occurred in any of the cases; clinical hypothyroidism did not develop. The results indicate that cobalt used in amounts up to 6 mg. per kilogram per day for 10 weeks does not affect any phase of thyroid function as measured by our radioactive iodine tests and has no goitrogenic action. Since cobalt, in vitro, in cell-free homogenates has been shown by Kirkwood and Fawcett [3] to inhibit tyrosine iodinase, the complete lack of antithyroid effect of cobalt in our experiments suggests that cobalt does not permeate the cells of the thyroid gland in vivo to a sufficient extent to affect gland function. Our results, of course, do not preclude the possibility of a rare idiosyncrasy or the possibility of some disease that would raise the cells of the thyroid to a state permeable to cobalt.

COBALTOUS CHLORIDE AND IODINE METABOLISM OF NORMAL AND TUMOR-BEARING RATS

Kenneth G. Scott, Ph.D.
and
William A. Reilly, M.D., San Francisco

Earlier studies have shown that transmissible tumors in rats and mice cause an alteration in the metabolism of radioactive iodine (I^{131}) and I^{131}-labeled compounds.[1] Animals bearing various transmissible tumors stored more I^{131} in their tissues than the controls. Additional studies upon this phenomenon showed the increased I^{131} uptake to be a local reaction at first. In the case of subcutaneous tumor implants, increased I^{131} uptake was observed only in the skin adjacent to the tumor. As the growing tumor exceeded a size of about 100 mg. the entire skin organ of the host became involved and took up more I^{131} than the controls.[2] As the tumor process proceeds, the iodide trapping by the tissues of the host increases to the extent that the excretion of iodide is markedly reduced. The extra thyroidal trapping of I^{131} interferes with thyroid function. The relationship between iodide trapping and tumor implant survival was established when it was shown that tumor implants in nonsusceptible rats did not elicit the iodide-trapping reaction even though they grew from 0.2 to 1.0 gm. prior to regression.[3]

In our efforts to screen agents that might block the undesirable trapping of iodide, which appears to be beneficial to the malignant process, attention was drawn to the in vitro studies of Kirkwood and Fawcett, in which they have shown that cobalt can inhibit such enzymes as iodotyrosinase.[4] It seemed desirable to investigate the effect of feeding cobalt to tumor-bearing animals since a polypeptide has been separated from tumor tissue that is associated with large amounts of free tyrosine and that binds I^{131}.

METHODS

Five young female Slonaker rats were used in each of the groups described below. Two groups were given cobaltous chloride and two groups given cobaltous chloride plus ferrous sulfate in their drinking water. One group given distilled water served as a control. All five groups were maintained on the above schedule for 44 days before they were killed. Thirteen days prior to the killing,

animals in group 1 (cobaltous chloride), group 3 (control), and group 4 (cobaltous chloride plus ferrous sulfate) received a tumor implant in each flank; this was a sarcoma that grows in the "ascites" form and enables uniform implants of 4.9 × 10⁶ cells to be administered to each rat. Sixty-six hours prior to the killing, a tracer dose of I^{131} was given to all groups, thus tagging the iodide pool of the animals. The presence of this radioactive tag made it possible to quantitate the conversion of the inert iodide pool into organically bound iodine as well as to study the complexing of iodide resulting from the tumor process. The release of protein-bound iodide to the blood stream of the rats was measured using an anionic exchange resin.[5] Selection of a 66-hour interval between I^{131} administration and sacrifice allowed ample time for the synthesis and release of thyroxin, and in part, reflected its rate of utilization. The tissues and excreta obtained were assayed for I^{131} with a scintillation counter.

RESULTS

The average daily water intake, body weights, packed cell volumes, and cobalt and cobalt plus iron intakes are presented in table 1 for comparison with controls. No appreciable difference in water intake was observed. The animals appeared to tolerate the cobalt well at the dosage level used. All of the rats gained weight at a normal rate. As was expected from the observation of Anderson and others[6] the animals receiving cobalt or cobalt plus iron had a polycythemia that is reflected in a larger than normal packed cell volume. The animals receiving cobalt and cobalt plus iron had tumors that weighed 67 and 70% of the controls. Cobalt or cobalt plus iron feeding significantly reduced tumor growth. P was less than 0.01 for both groups, when they were compared to their controls.

The uptake of I^{131} by the thyroids of all five groups of rats fell within normal limits. The greater than normal thyroid uptake by the tumor-bearing animals is typical for this time period because the maximal uptake is attained at a later time than the normals. These data are presented in table 2 with the I^{131} content of the other specimens measured. The greater than normal I^{131} content of the tissues of the tumor-bearing rats is typical for the time period selected after I^{131} administration and is due to the malignant process. The increased uptake is presumably due to the iodide-binding action of the tumor polypeptide, which has been demonstrated in human, mouse, and rat tumors.[2] All groups of rats had detectable amounts of I^{131} in their plasma. From 23 to 51% of the total I^{131} was present as protein bound iodine. No significant difference was observed between protein bound I^{131} in plasma of the cobalt-treated animals and their controls. The rats receiving cobalt retained more of the I^{131}

tag in the tumor tissue than their controls. This effect has not been explained. Further studies are in progress in order to investigate this difference.

COMMENT

Within the scope of their limitations, these studies confirm those of others,[6] indicating that the administration of cobalt or cobalt plus iron is capable of stimulating hematopoiesis in the rat to a significant degree. In addition this regimen inhibited tumor growth significantly, although the results were not dramatic. No inhibition of I^{131} thyroid uptake, thyroxin synthesis, hormone release, or circulating hormone levels were observed following cobalt feeding. Owing to the fact that the growth of the young rats in the several groups described was well within normal limits for this strain of rat, it must be concluded that hormone utilization was essentially normal. Comparative studies upon thyroidectomized rats of the same strain in this laboratory indicate that adequate thyroid tissue is essential for normal growth.[7] It has also been observed by Levine and co-workers [8] that inadequate iodide diets cause young rats to develop severe goiter in four to five weeks. No evidence of goiter was observed in the cobalt-treated animals at the time of killing.

SUMMARY

The addition of cobaltous chloride to the drinking water of rats in order to maintain a daily intake of 60 mg. per kilogram of body weight had no appreciable effect on their iodine metabolism. Similar results were obtained with a mixture of cobaltous chloride (60 mg. per kilogram) and ferrous sulfate (57 mg. per kilogram). At the dosage levels described above, a pronounced polycythemia was observed after 44 days of cobalt administration. No deleterious effect was observed upon thyroid function or growth. The administration of cobaltous chloride at the dosages used in this study significantly retarded the growth of a transmissible fibrosarcoma.

ALIEN INTERNS AND RESIDENTS IN THE UNITED STATES

James E. McCormack, M.D.
and
Arthur Feraru, D. en D. de L. U. (Lyons), New York

For the past several years various agencies have been interested in evaluating the status of physicians trained abroad who have come to this country either as *émigrés* or as temporary visitors in search of further training. Several statistical studies have been reported that indicate that the number of foreign-trained physicians occupying house officer positions is increasing. For the year 1953-1954, estimates ranged between 5,500 [1] and 6,000 [2] such physicians, who constitute between one-fifth and one-fourth of the total interns and residents on duty in the hospitals of this country.

NONIMMIGRANT PHYSICIANS

In the earlier reports referred to, it was not feasible to separate immigrant physicians from those foreign-trained physicians who were here on nonimmigrant visas for a limited period of hospital training. Furthermore, it has not always been possible to be sure that collected data omit duplications. One of the difficulties experienced by many hospitals in arranging a training program is the tendency for alien physicians to arrive at odd times to begin training, whereas the average American intern or resident starts his period of service on July 1 or Jan. 1. Furthermore, as hospital administrators know, certain alien physicians have been known to move from one hospital to another with little regard to whether there had been an obvious or implied commitment to stay for a full year. Thus it is conceivable that a small amount of duplication entered into the earlier studies in instances where such a physician left one hospital after that hospital had completed an annual questionnaire and arrived at a second hospital in time to be included in its listing because the second hospital was somewhat late in completing the same questionnaire. The present study, which was conducted by the Institute of International Education with the cooperation of the American Medical Association, was designed to eliminate any duplication and to omit foreign-born interns and residents who are in this country as immigrants. The instructions accompanying the inquiry requested that there be included only interns and residents who have both foreign citizenship and permanent residence in a foreign country. All others, such as displaced persons who might be in hospital positions, are omitted. To be more specific, hospitals were instructed to omit: (1) persons from Alaska, the Hawaiian Islands, Puerto Rico, the Virgin Islands, Guam, or other United States territories; (2) displaced persons resettled permanently in the United States; and (3) foreign citizens who have immigrated to the United States for permanent residence.

It is entirely possible that some of the aliens in this study may eventually acquire immigrant status; however, so far as we are able to tell, only persons who are by definition true aliens are included. If this report were in any way intended to evaluate medical education one would prefer not to include Canadians, since Canadian medical education is in all instances similar to American. Furthermore, like other Americans, we find it difficult to think of our Canadian colleagues as in any sense

---

Associate Dean, Graduate Studies, Columbia University College of Physicians and Surgeons (Dr. McCormack) and Head of the Central Index and Census Division, Institute of International Education (Mr. Feraru).

[2] McCormack, J. E.: The Problem of the Foreign Physician, J. A. M. A. 155: 818 (June 26) 1954.

alien; however, we do not know the medical schools attended by the individuals included in the study, and it is possible that some of the house officers listed as citizens of Canada had previously lived and studied in other countries abroad. In September, 1954, an inquiry was sent to all the hospitals approved by the American Medical Association for intern or resident training. A follow-up communication was sent in November. Replies were received from 90% of the hospitals to which the communication had been sent.

In order to estimate the completeness of the returns, the names of the physicians brought to this country in 1954-1955 by the Ventnor Foundation were checked against our returns. Of 63 persons on the foundation list who were in this country at the time of our survey, 57 were identified in our data. This is one indication of the degree to which our data are complete. The Ventnor Foundation sponsors one of the most carefully supervised programs that has come to our attention. Initiated by Dr. and Mrs. Hilton S. Read of Atlantic City, N. J., this effort brings to this country for a period of hospital training young German medical graduates who are carefully screened, have high scholastic records, and are proficient in English. Obviously our returns are not complete, but they are reported for what they may be worth and for evaluation in relation to other studies so that eventually all concerned may have a clearer picture of the status and the trends in the training of foreign-born physicians who may come to this country.

TABLE 1.—*Alien Physicians Training in Approved Hospitals in the United States, 1954-1955, by States and Territories*

Location of Hospital	Total No. of Doctors	Location of Hospital	Total No. of Doctors
Alabama	12	New Jersey	348
Arizona	42	New Mexico	..
Arkansas	5	New York	1,186

Numbers.—The questionnaire was sent to the 1,315 hospitals listed by the Council on Medical Education and Hospitals as approved for internship or residencies or both. Replies were received from 1,177 (89.5%), of which 743 were positive and 434 negative. Thus, at least 56.5% of the approved hospitals are known to have aliens on the house staff, and 33% report no aliens.
Of the group of hospitals reporting, 63% have alien
terns or residents. Some of those reporting no al
may have immigrants on the house staff, but this re
is not concerned with immigrants. Incidentally, it
reported at the Congress on Medical Education
Licensure in Chicago in February, 1955, that a small
definite proportion of alien physicians are in hosp
not included in the approved list of the American M
cal Association employed in the present study.

The data indicate that for the current year 1954-1
there are at least 5,036 alien physicians in training in
proved hospitals (4,416 males and 620 females). T
are 1,761 interns, of whom 1,528 are male and 23
male; there are 3,275 residents, of whom 2,888 are
and 387 female. Females constitute 12.3% of the g
(13.2% of interns and 11.8% of residents), whe
females constituted from 5.2 to 5.7% of the graduat
American medical schools during the three years 1
through 1954. The percentage of females was sig
cantly higher among the house officers who had c
from the following countries: China 21%, India 1
Greece 18%, Korea 25%, Philippines 25%, Ur
Kingdom 28%. Of all the females, both interns
residents, 57% came from the Near, Far, and Mi
East, the Philippines contributing the greatest num

Fields of Study.—Among residents there were
ported no less than 33 different titles of specialtie
fields of study. The 10 most frequent were, in or
general surgery, general medicine, obstetrics and
ecology, pediatrics, pathology, psychiatry, anesthe
ogy, internal medicine, radiology, and otolaryngol
Comparison with the relative number of approved
dencies in the various specialties in this country i
cates no particular pattern of interest; however,
number of aliens training in the following specialti
relatively high in relation to the number of appr
residencies in these specialties: thoracic surgery, tu
culosis and pulmonary disease, plastic surgery, ne
surgery, otolaryngology, and anesthesiology. It woul
unwarranted to draw many conclusions from this
observation, since the relationship is drawn with
number of approved residencies rather than with
number of such residencies occupied.

Distribution.—A small number of these physic
(28) are in seven hospitals outside the continental Un
States (five in Hawaii and one each in Puerto Rico
the Canal Zone). Hospitals in these areas are inclu
in the American Medical Association list. The numl
involved are so small as not to affect the results, but t
are included for completeness and for valid compari
with future studies that may be based on the listing
hospitals approved for the training of interns and r
dents published annually in THE JOURNAL.

Table 1 indicates that 42 states and the District
Columbia reported the presence of alien house offic
and only 6 states did not report any: Idaho, Monta
Nevada, New Hampshire, New Mexico, and Wyomi
of these, Idaho, Nevada, and Wyoming have no
proved internships or residencies, and the others ha
only a few approved residencies. The 10 states hav
the largest numbers were New York 1,186, Ohio 4
Massachusetts 405, Illinois 396, New Jersey 348, Pe

sylvania 262, Missouri 216, Michigan 184, Maryland 172, and California 160. This is in accord with the pattern in previous studies.

Origin and Sponsorship.—These visitors came from 83 different countries as indicated in table 2. There are included 1,983 from 22 countries in the Far, Near, and Middle East; 1,229 from 28 European countries; 297 from 4 Caribbean countries; 909 from the Latin American mainland, including Mexico, 7 Central American countries, and 11 South American countries; 520 from Canada; and 54 from 8 African countries. The 12 countries having the largest representation are: Philippines 776, Canada 520, Mexico 425, Germany 323, Turkey 253, Italy 242, Cuba 184, China 170, India 165, Korea 151, Greece 144, and Japan 139.

An effort was made to determine under what sponsorship these individuals had come to this country. There were at least 67 different sponsoring agencies (excluding hospitals), but the replies indicated that the great majority of persons were here on their own resources. Of the 5,036 physicians in the study, 1,932 did not give any answer. Of the remaining 3,104 persons, 2,606 indicated that they were here on their own resources. One hundred indicated that they came under the sponsorship of one or another of 10 different agencies of the United States government. Thirty-one came under the sponsorship of 18 foreign governments (the government of the doctor's home country). One came under United Nations sponsorship. Ninety-eight came under sponsorship 8 different groups and organizations—religious, eduonal, or philanthropic—either American or foreign. ne 268 indicated that their sponsor was the hospital vhich they were receiving training.

ctually, of the 4,538 who either gave no answer or icated that they had come on their own initiative, it easonable to guess that most of them have sponsor- of the hospital in which they are serving, or perhaps, he case of university-affiliated hospitals, sponsorship a university. The reason for this assumption is that, rder to obtain an exchange-visitor visa, the individual st have sponsorship of some institution. Since the hange-visitor regulations were promulgated in 1949, ne 1,850 privately sponsored exchange-visitor proms have been designated, of which over 1,000 are nsored by American hospitals and allied institutions viously for the purpose of enabling the institutions to vide training for foreign nationals.

OTHER PROFESSIONAL VISITORS

In addition to the large number of physicians who me to America from abroad for hospital internshipidency training, there are many physicians who come this country on nonimmigrant status for varying pe-ds of time as observers, visiting professors, guest rticipants in research, or in other capacities. The anal survey of foreign professors, instructors, and lecrers in the United States conducted by the Institute of ternational Education for 1954-1955 indicates that at ast 137 of these visiting educators are listed under nedicine." This is the largest separate group and presents 21.5% of 635 visitors reported. Like the ien house officers, these people come from all parts of e world, are widely distributed in this country, and have sponsorship from diverse sources. Even this does not afford a complete picture of the degree to which this country has become a medical magnet. Many of the major teaching centers, especially in the large metropolitan areas, could very quickly assemble in the course of a year a list of 100 or more alien physicians who have visited for brief periods, either on the occasion of attendance at some international medical meeting in this country or Canada or as part of a tour arranged by the World Health Organization, or the Foreign Operations Administration, or various religious and philanthropic groups. To complete this picture, the Institute of International Education conducted a survey of United States professors, instructors, and lecturers abroad during the academic year 1954-1955. This study reveals 1,047 American scholars visiting all parts of the world, of whom 38 (only 3.6%) are listed under "medicine."

SUMMARY

The number of nonimmigrant foreign physicians who are in this country for hospital internship-residency training during the year 1954-1955 exceeds 5,000; about one-third are interns and two-thirds residents. They came from 83 different countries in all parts of the world. The percentage of females, particularly from certain European and oriental countries, is significantly higher, than the proportion of females among American medical graduates. These visitors are located in all except six states. If Canadian doctors were omitted from this survey, the total reported would be reduced to 4,516, but the distribution would not be appreciably altered, since Canadians are found in 30 states, the District of Columbia, and the Territory of Hawaii. A relatively high percentage of these visitors from Canada, however, are in residencies (443 or 85%) and only a limited number in internships.

630 W. 168th St. (32) (Dr. McCormack).

CLINICAL NOTES

POLYCYTHEMIA ASSOCIATED WITH UTERINE MYOMAS

Alec Horwitz, M.D.
and
William P. McKelway, M.D., Washington, D. C.

Thomson and Marson [1] recently reported an unusual case of serious polycythemia associated with a large myoma in a 48-year-old woman. The blood picture returned to normal after abdominal hysterectomy. A review of the literature failed to reveal a similar case. This prompts us to report a similar experience, in which the removal of a large myoma caused the disappearance of a severe secondary polycythemia, and also a case of polycythemia vera, in which hysterectomy with the removal of several myomas failed to affect the blood picture.

REPORT OF CASES

Case 1.—A 47-year-old white widow was first seen because of gradual enlargement of the abdomen, over a period of three years. Her last menstrual period was at the age of 45, with normal menopause occurring at that time. There were no associated symptoms except for fulness and burning following meals. Her history revealed an appendectomy at the age of 43. There was no other operation or serious illness.

Physical examination revealed a short, stocky, plethoric white female, height, 4 ft. 10 in. (147.3 cm.), weight, 135 lb. (61.2 kg.). Her temperature was 98.6 F, pulse 110 per minute, respirations 20 per minute, and blood pressure 150/90 mm. Hg. There was marked rubor of the skin and mucous membranes. The heart and lungs were clear. A huge tumor filled the abdomen from symphysis to xiphoid. Pelvic examination revealed the tumor to be directly connected to the uterus and cervix, filling the pelvis. An electrocardiogram revealed myocardial strain with sinus tachycardia. Fluoroscopy showed the heart to be enlarged slightly to the left, with elevation of both leaves of the diaphragm. Circulation times were normal. Blood studies were reported as shown in the following tabulation. The hematocrit, taken July 13, 1952, was 44%.

At operation, April 13, 1944, an intraligamentous, 18 lb. (8,164.7 gm.) myoma arising from the right cornu of the uterus was removed. The tumor was very vascular, with several large veins measuring up to 1 in. in diameter coursing over its surface. There was minimal blood loss associated with the procedure. An interesting feature of the tumor was that it showed fibrillary twitching for 19 hours after its removal. Pathological examination confirmed the diagnosis of a highly vascular myoma.

The patient's postoperative course was uncomplicated except for an episode of thrombophlebitis with a febrile course of two weeks' duration. On July 9, 1952, the patient was admitted to the hospital for varicose vein ligation and stripping. This admission was uneventful, and, as shown in the following tabulation, the blood picture had remained normal at this time, eight years after the initial operation.

Date	Red Blood Cells, Millions	Hemoglobin, % *	White Blood Cells
4/ 8/44	10.4	116	......
4/12/44	8.5	141	......
4/14/44	5.7	105	12,000
5/13/44	4.3	75	8,500
7/ 9/52	5.0	90	9,100
7/13/52	...	98	7,500

* First 4 determinations made by Dare's method (116% ≃ 18.6 gm. pe 100 cc.); last 2 determinations by Sahli's method (90% = 14 gm. pe 100 cc.).

Case 2.—A 32-year-old white female was first admitted t the hospital in June, 1950, because of subacromial bursitis. A the time of her admission it was discovered that her red bloo cell count was exceptionally high, with a hematocrit of 57% Physical examination revealed hepatosplenomegaly. One yea later, it was noted that the patient had small uterine myoma that were asymptomatic. After this, the patient develope gradually increasing menorrhagia and a relative anemia. Sh was admitted to the George Washington University Hospita May 3, 1953. The admission physical examination was essentially normal except for moderate anemia, hepatosplenomegaly and a multinodular uterus, which measured approximately 1 by 12 cm. in diameter.

Total abdominal hysterectomy was performed on the secon hospital day. The patient had a greatly enlarged spleen tha extended down to the level of the umbilicus and an enlarge liver. The uterus had several irregular myomas, which were bot subserous and intramural. Pathological examination confirme the diagnosis of uterine myomas. The patient's postoperativ course was uncomplicated, and she was discharged on the sevent postoperative day. The blood cell counts failed to return t normal levels after correction of the relative secondary anemi and tended to assume limits consistent with polycythemia, the operative procedure apparently having had no effect on the previous blood picture. Blood studies gave the following results:

Date	Red Blood Cells, Millions	Hemoglobin, % *	White Blood Cells
2/12/51	6.5	120	22,300
2/15/51	6.3	110	22,200
4/18/51	5.2	104	23,000
4/25/53	4.0	62	14,500
6/ 9/53	4.4	83	16,900
10/ 3/53	5.0	91	14,900

* Alkaline-heme-photoelectric method (120% = 18 gm. per 100 cc.).

Bone marrow studies preceding and following the operative procedure showed erythroblastic hyperplasia, consistent with polycythemia vera.

COMMENT

Since 1948, nine female patients have been admitted to the George Washington University Hospital with the primary or secondary diagnosis of polycythemia. In no instance, other than the two cases recorded here, was there evidence of other uterine pathology or gynecologic disease. In an attempt to further correlate the presence of uterine myomas with polycythemia, records were re-

---

From the Department of Surgery and the Department of Obstetrics and Gynecology, the George Washington University School of Medicine and Hospital.

[1] Thomson, A. P., and Marson, F. G. W.: Polycythaemia with Fibroids, Lancet 2:759-760 (Oct. 10) 1953.

viewed of 200 patients admitted during the past five years for hysterectomy because of myomas. There was no evidence of polycythemia in any of these nor was there any apparent connection between blood cell count and size of myoma. The first case reported is a secondary polycythemia that was cured by the removal of a large myoma. The reason for this result is obscure. The tumor was highly vascular, both grossly and microscopically, and the possibility of arteriovenous shunt within the tumor exists. The second case is one of polycythemia vera. The patient's menorrhagia represented an effective though uncomfortable method of control of elevated blood cell count. The hysterectomy has caused no change in the polycythemia vera.

SUMMARY

This is the second recorded case of secondary polycythemia cured by the removal of a large uterine myoma. A case of polycythemia vera, which was not cured by hysterectomy for myomas, is also reported. The possibility of arteriovenous shunt within the tumor is postulated as a cause for secondary polycythemia.

23rd Street at Washington Circle (7) (Dr. Horwitz).

A NEW TECHNIQUE COMBINING SUCTION AND FEEDING FOR USE IN GASTRIC SURGERY

I. Ridgeway Trimble, M.D.
and
John Nouri, M.D., Baltimore

Some safe and simple combined method of drainage and feeding after gastric operations has long been needed. First of all, the method should be comfortable and not irritating to the patient. Next, the method should drain any excess of retained secretions within the stump of the stomach in order to prevent vomiting, avoid gastric dilatation, and avoid excessive pressure on the line of anastomosis. The method should also drain any excessive secretions from both the afferent and the efferent jejunal limbs in order to prevent undue pressure on the closed duodenal stump and in order to be in a position to release pressure in the distal jejunal limb by suction if some paralytic ileus should develop. At the same time the method should permit all fluids and feedings to be given through the alimentary tract from the moment that the operation has been completed.

A review of appliances heretofore used or described shows that no one of them fulfills each of the desired requirements. Several types of double lumen tubes have been devised. These can drain the stomach and can enter into only one limb of the jejunum for purposes of feeding or suction. A Y tube leading from the stomach into each jejunal limb is suitable for suction but obviously could not be used for feeding. One double lumen catheter had a tiny plastic tube that could be used for feeding but had a lumen so small that fluid could be injected into it only through a needle, and it was so light that a metal bulb had to be placed on its jejunal tip in order that the small feeding tube was not regurgitated back into the stomach. No appliance heretofore described permits the removal of the suction mechanism before the feeding mechanism.

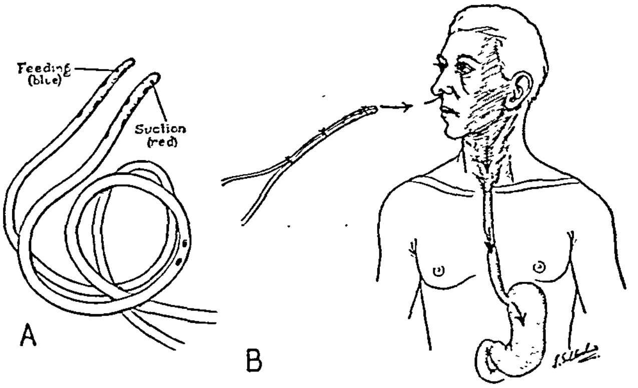

Fig. 1.—*A*, feeding tube painted blue on both ends with perforations near tip only. Suction tube painted red on both ends with perforations near tip and also at 20 cm. from tip to drain gastric stump as well as proximal jejunal loop. *B*, two no. 12 polyvinyl tubes tied together with three silk sutures; easily passed down through one nostril into the stomach.

The method of suction and feeding described here consists of two polyvinyl tubes of small caliber (12 F.) tied together and inserted before operation through one nostril down into the stomach (fig. 1). When an end-to-side anastomosis is being made between the stomach and the jejunum, the tubes are drawn down through the open gastric stump after the two posterior rows of sutures have been completed. The three silk ties are then cut, thereby separating the catheters (fig. 2). The catheter dyed red at both ends and stamped with the word "suction" is led down about 20 to 25 cm. into the proximal limb in order to drain the duodenal, pancreatic, and biliary secretions and take pressure off the closed duodenal stump. This catheter has additional holes in it to drain the gastric stump. The catheter dyed blue at both ends and stamped with the word "feeding" is led into the distal limb of the jejunum for 20 to 25 cm. and is used for giving water, saline solution, glucose solution, and a liquid diet. It can also be used for suction of the distal limb of the jejunum, should this prove desirable.

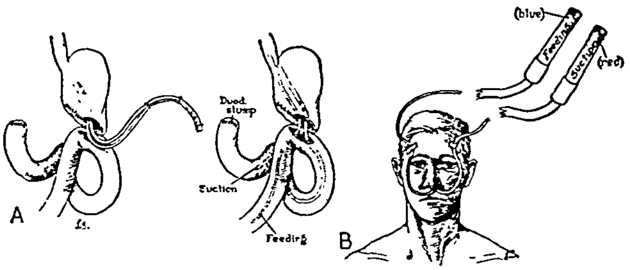

Fig. 2.—*A*, tubes are drawn down through gastric stump and the silk sutures divided; suction tube is passed down into proximal loop and feeding tube into distal loop. *B*, patient after operation, with tubes ready for use.

The polyvinyl tubes used in this study were specially constructed by the American Cystoscope Makers, Inc., New York 59.

If the operation unites the stomach end-to-end with the duodenum, the so-called Billroth 1 operation, this combination of suction and feeding is equally applicable. The suction tube is then left in the stomach and the feeding tube advanced into the duodenum.

The two small tubes tied together are just as easily inserted into the nostril as the single large tube now universally employed. For the patient's comfort, we usually spray the nostril with a mild local anesthetic before insertion. In all our cases we have used the no. 12 tube for feeding. In some we have used the next larger size, no. 14, for suction, but no. 12 has not become plugged when used for suction or feeding.

Among the advantages of this particular apparatus are: (1) drainage of the stomach; (2) drainage of the proximal loop of the jejunum; (3) drainage of the distal loop of the jejunum; (4) feeding of the patient through the jejunum; (5) refeeding where thought desirable of contents of gastric suction down feeding tube; (6) stabilization of all three limbs of gastrojejunostomy, reducing possibility of postoperative stomal obstruction; (7) aiding of early intestinal peristalsis; (8) nonirritating quality, small size, and light weight of tube; (9) avoidance of intravenous therapy; and (10) simplicity of apparatus.

All the above advantages seem rather obvious. The voidance of intravenous therapy has several good features that are worthwhile pointing out. These are derived from being able to give water, electrolytes, and food directly into the gastrointestinal tract rather than into the veins, thereby restoring the patient's metabolism most effectively, relieving the patient of the discomfort of long continuous hours of intravenous feeding, permitting earlier and more frequent ambulation, diminishing strain on the heart, diminishing the instance of phlebitis and other reactions incident to intravenous therapy, and conserving the time of the residents and nursing staff.

FEEDING AND SUCTION

Immediately after operation the blue tube marked "feeding" is connected to a slow drip of saline solution before the patient leaves the operating room. On the day of operation and on the day after operation the entire fluid, glucose, and electrolytic requirements are given through this jejunal tube. For the average adult patient, the feeding drip is started at 60 drops (4 cc.) a minute. This rate gives 240 cc. per hour and 2,880 cc. per 24 hours. Forty-eight hours after operation a high-protein, high-carbohydrate liquid diet is given through the feeding tube. Each 1,000 cc. of this diet contains 1,000 calories of food value. Each 24 hours we give a mixture of 1,500 cc. of this diet diluted in 1,500 cc. of water, a total of 3,000 cc. of liquid containing 1,500 calories. The feeding tube is usually kept down four to six days, at which time oral feedings are given. Feedings may be given through the tube in larger quantities, such as 120 cc. every half hour or 240 cc. every hour, rather than by the drip method, if this seems desirable in the individual patient.

Immediately after operation, the red tube marked "suction" is connected to gentle bedside suction. In the next 24 to 48 hours this tube can be clamped off periodically to see if it is still needed. When it is no longe needed, it can be withdrawn without having to remov the feeding tube. Suction can also be applied to th feeding tube that lies in the jejunum, if this is ever necessary, as in paralytic ileus.

This combination of feeding and suction has bee used in a relatively small number of cases of gastric resection to date. In every case it has proved most helpfu In no case, even one of radical resection of the head o the pancreas, has any postoperative intravenous therap with fluids been necessary. Daily studies of serum protein, chloride, sodium, and potassium have show prompt return to normal levels in the immediate postoperative period. The patients have all tolerated the small plastic tubes very well, apparently with less discomfort than the single larger rubber tube.

SUMMARY

A simple method for use in gastric surgery that permits a combination of suction to the stomach and afferent jejunal limb and feeding through the distal jejunal limb has proved highly successful in all patients on whom this technique has been used.

8 W. Madison St. (1) (Dr. Trimble).

DIAGNOSTIC PROBLEMS

PRESENTATION OF CASE

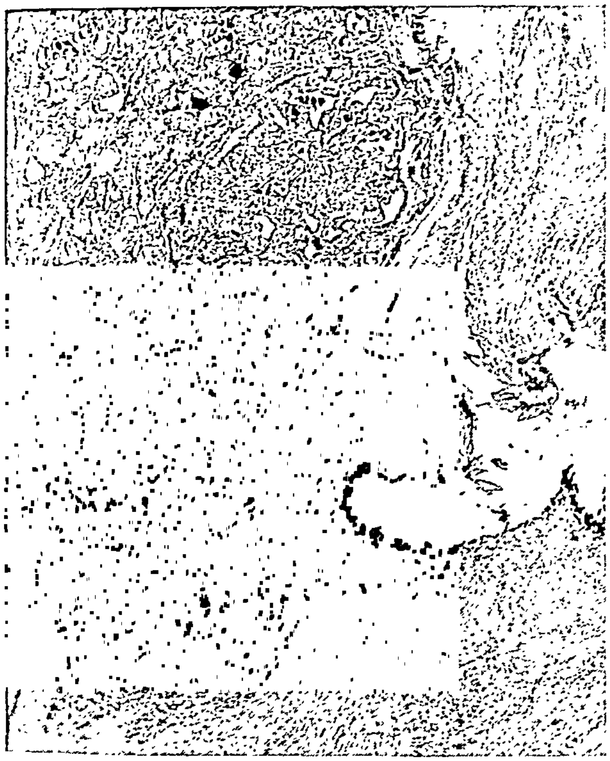
John D. Thorpe, M.D., St. Louis

A 34-year-old housewife entered Barnes Hospital for the first time on June 25, 1954. About one year prior to admission she had noted a lump in the region of the right lobe of her thyroid. This was about 0.5 in. (1.27 cm.) in diameter and nontender. There had been no alteration in its size. After a death in the family in March, 1954, she became increasingly nervous, anorexic, and lost 17 lb. (7.7 kg.) in weight. She consulted her family physician and was hospitalized for diagnostic studies. The only significant findings were a slightly enlarged thyroid with a palpable nodule in the right lobe near the isthmus. The basal metabolic rate was within normal limits on three occasions. After her discharge she regained her normal weight, but her nervousness continued, and, on June 4, she was referred to a surgeon for removal of the thyroid nodule. This was done as a local excision. The surgical specimen measured 2 cm. in diameter and microscopically revealed a papillary adenocarcinoma. The patient was then referred to Barnes Hospital for further treatment.

Physical Examination.—The patient had a recent healing surgical incision across the lower anterior portion of her neck. The left lobe of the thyroid was slightly enlarged. No significant lymphadenopathy was present in the neck. There were no clinical signs of hyperthyroidism. Laboratory examinations were within normal limits.

From the Department of Surgical Pathology, Barnes Hospital.

Course.—On the following day, total thyroidectomy was performed, with an excision in continuity with the scar of the previous surgical incision. The sternohyoid and sternothyroid muscles were divided at their points of origin on the sternum and a block dissection of the thyroid gland and adjacent soft tissues was performed. Parathyroid tissue was identified bilaterally and preserved. No lymph nodes suspected of harboring metastatic lesions could be palpated in either deep cervical chain. Microscopic examination of the surgical specimen disclosed a persistence of the papillary adenocarcinoma confined to the isthmus and a foreign body reaction to the suture fragments present after the first surgical excision (see figure). Postoperatively, the patient developed mild symptoms of parathyroid insufficiency, which responded to calcium lactate therapy. She was discharged improved seven days after the operation. Calcium lactate by mouth and a low phosphorus diet were prescribed. There were no residual hypoparathyroid symptoms at the time of discharge.



Persistent cancer in the isthmus of the thyroid. Note proximity of the carcinoma to suture fragments.

COMMENT

Charles Eckert, M.D., St. Louis

It is generally agreed that the incidence of malignancy in nontoxic nodular thyroids is significantly greater than in other clinically evident thyroid diseases. This figure reaches prominence when a solitary thyroid nodule is considered. Reliable statistics [1] indicate that in surgically excised single nodules an average of 20% prove to be malignant. A rapidly enlarging nodule or one that is firmer in consistency than the surrounding thyroid tissue should not be disregarded; delay may only serve to prevent cure. Despite accurate physical examination and laboratory studies, a satisfactory diagnosis frequently necessitates surgical exploration. Good operative judgment in the planning of the technique to follow can prevent future difficulties. Excision of the nodule with a generous margin of normal thyroid tissue if the nodule is small, or by lobectomy if it is large, should be performed. Frozen section at this time can be advantageous.

Although the prolonged clinical evolution that characterizes certain malignant thyroid tumors has been used as an argument to justify a conservative surgical approach in their management, many patients with these tumors ultimately succumb to their disease, either by local invasion of adjacent vital structures or by distant metastasis. The failures of too limited a surgical procedure are, unfortunately, often discovered too late to offer the patient more than temporary palliation. Adequate surgical removal is the treatment of choice. External roentgenotherapy has not given satisfactory results as a primary treatment, nor has it proved to be of value when used postoperatively to supplement an adequate surgical procedure.

The clinical finding of a solitary nodule in the thyroid is an indication for further study to define the exact nature of the pathological process. This can only be accomplished by operative exposure and the removal of tissue for pathological examination. The surgeon must examine the entire thyroid gland, as well as palpate the deep cervical lymph nodes. It is therefore necessary to expose the area through an adequate transverse incision placed in a convenient skin crease in the lower part of the neck. Under no circumstance should small incisions be used for direct exposure of the nodule alone, limiting the examination of the entire gland. When a solitary nodule is found in the isthmus, as in the case here described, the entire isthmus should be removed. If a lateral lobe is involved, a lobectomy should usually be performed. In doing this the recurrent laryngeal nerve should be identified and preserved. Incisional biopsy is to be avoided in order to minimize the possibility of the implantation of tumor cells within the operative field. Immediate frozen section by a competent surgical pathologist will be of great assistance to the surgeon in deciding the necessity for further measures when the pathologist is able to make a definite diagnosis of cancer. This can frequently be accomplished in the papillary tumors and in undifferentiated carcinomas. In the case of the well-differentiated follicular tumors, great difficulty in diagnosis by frozen section may be encountered, as indeed great difficulty may be found in making this diagnosis with permanent sections.

When a diagnosis of papillary carcinoma of the thyroid has been established, total thyroidectomy is indicated because of the finding of multiple foci of origin in one or both lobes.[2] These foci may be exceedingly small; therefore, palpation of the exposed thyroid cannot be depended on for their discovery. Neck dissection in treating a papillary carcinoma is indicated when lymph nodes clinically suggestive of harboring metastases are palpable. Follicular tumors metastasize to regional lymph nodes less frequently than do the papillary tumors, but, if lymph

---

From the Department of Surgery, Barnes Hospital.

nodes clinically suspected of harboring metastases are palpable in the lateral portion of the neck, a dissection of this region is indicated.[3] The undifferentiated carcinomas have an exceedingly poor prognosis, but, in the rare case in which vital structures have not been invaded or distant metastasis has not occurred, adequate surgical removal can control the tumor. With a carefully planned and skilfully executed surgical procedure, operative and postoperative complications can be minimized and the patient will be given the maximum chance of being cured.

COUNCIL ON PHARMACY AND CHEMISTRY

EPORT TO THE COUNCIL

The Council on Pharmacy and Chemistry has authorized publication of the following reports.

R. T. STORMONT, M.D., *Secretary.*

The following articles are the most recent additions to the series of reports on pesticides of immediate medical interest. The Committee wishes to acknowledge the assistance of Drs. Wayland J. Hayes Jr. and Francis F. Heyroth in reviewing the manuscript and the contributions of records of poisoning by Drs. Ted Clemens Jr., Amos Graves, George Miners, and David A. Todd and Mr. Allen B. Lemmon.

BERNARD E. CONLEY, *Secretary,*
Committee on Pesticides.

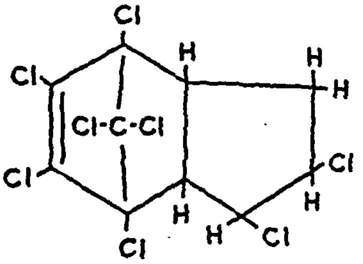
THE PRESENT STATUS OF CHLORDANE

Chlordane is a chlorinated hydrocarbon insecticide that has been subject to much legal and scientific controversy. It has been a variable product available as an impure mixture by either of the two available methods of manufacture. One of these methods, now abandoned because of patent conflicts, is said to have been a less efficient procedure and left more impurities in the commercial product.

The insecticidal properties of chlordane were independently discovered almost simultaneously in the United States and in Germany. The American product was developed and tested during World War II, and commercial production began shortly after hostilities ceased. A German preparation designated as M-410, with a formula similar to chlordane, was developed in 1945. It was synthesized and tested as an insecticide because of structural similarities to cantharidin, a vesicant principle in Cantharis vesicatoria, the blistering beetle, which in dried form has been used as an irritant drug and contact insecticide. Because of chemical shortages and patent restrictions, the German product has not been prepared in commercial quantities.

PROPERTIES

Chlordane is the common name generally accepted for the chemical compound 1, 2, 4, 5, 6, 7, 8, 8-octachloro-4, 7-methane-3a, 4, 7, 7a-tetrahydroindane. It is a heavy, dark brown, oily liquid that is insoluble in water but soluble in the common organic solvents. In common with other chlorinated hydrocarbons, it is unstable in the presence of weak alkalis, and dehydrohalogenation occurs with a consequent loss of insecticidal activity. The structural formula may be represented as follows:



Technical chlordane, the commercially manufactured product, contains 60 to 75% chlordane and 25 to 40% related compounds. There are at least eight theoretically possible stereoisomers of chlordane of which the alpha and beta isomers have been separated by chromatography. A so-called gamma isomer has been reported but was later found to be identical with the alpha isomer. It is about 70% as active as the technical mixture.

A variety of other constituents have been identified in the mixture normally resulting from the manufacturing process. These compounds include chlordene, the mono and trichloro derivatives of this chlordane precursor, and reaction intermediates such as hexachlorocyclopentadiene. Full information on the biological properties of these compounds is not available, but enough is known to indicate that many contribute to the insecticidal activity and in certain instances to the harmful properties of the finished product. The newer insect toxicant, heptachlor, was originally isolated from this uncharacterized fraction of the commercial mixture.

The technical product is a viscous, pungent, amber-colored liquid that is available in two grades, agricultural and refined. The agricultural mixture is a thick, syrupy liquid that is used whenever the staining of treated surfaces is not a problem. The clarified grade is less viscid and of a lighter color and is generally used for the control of household insects. Lethal action on susceptible organisms results from contact, ingestion, or exposure to chlordane vapors. The volatile properties and residual characteristics of chlordane are intermediate between those of chlorophenothane (DDT [dichlorodiphenyltrichloroethane]) and gamma benzene hexachloride.

USES

Chlordane is effective in the control of certain agricultural and household pests and for the abatement of various arthropods of public health importance. It is available in the form of oil solutions, emulsion concentrates, wettable powders, and in insecticidal dusts, paints, and waxes.

Agricultural uses of chlordane include the control of grasshoppers, cotton insects, and certain pests affecting livestock and soil. It is not accepted for use on food crops during periods of growth when edible parts are present or on forage, hay, or silage crops intended as feed for dairy animals, poultry, and meat animals being readied for slaughter. Recommendations against such uses are predicated on dangers associated with the ingestion of small deposits of the substance in food crops or their retention in milk, eggs, or body tissue of slaughtered animals. A tolerance of 0.3 ppm has been established under the federal Food, Drug and Cosmetic Act as the limit on the amount of chlordane that may appear on or in specified fruits and vegetables.

Chlordane has not been accepted as a space spray against flying insects. It is registered for use as a residual application against ants, flies, mosquitoes, roaches, and certain other household insects in 3% concentrations (emulsions and solutions) and 6% dusts. Because of its fumigant properties and chronic toxicity, recommendations for residual use in homes are limited to spot treatment of selected indoor surfaces such as around baseboards, doors, and windows in the kitchen. It is not approved for over-all treatment of interior surfaces because slow liberation of fumes, especially in closed heated rooms, constitutes a danger to persons regularly exposed. Special care should also be taken to avoid deposits on areas frequently contacted by children. Newly treated lawns may constitute a special problem in this respect unless the chemical has been thoroughly washed into the soil after treatment.

No medicinal use for chlordane in the pure form or technical mixtures has been found acceptable to date. It has been proposed for use in the treatment of pediculosis capitis and scabies, but the high dermal toxicity of the compound after repeated use has discouraged serious consideration for these purposes.

PHARMACOLOGY

A complete pharmacological evaluation of technical chlordane is difficult because it is not a definite chemical entity. The commercial products have been variable mixtures of several chlorinated hydrocarbons, some of which have not been identified and are not always present in the same proportions. The indefinite composition of even current productions of the technical preparation increases the difficulties of assessing chlordane's intrinsic metabolic nature and precludes all but the broadest generalities concerning its action and fate in the animal body.

In general, chlordane acts substantially like other chlorinated hydrocarbon insecticides whose sites of action are on the higher motor cortex and the cerebellum. It does not affect vital centers in the medulla. In contrast to chlorophenothane and its derivatives, there appears to be little correlation between the chlorine content of the mixture and its biological activity. No pronounced antagonism or synergism is observed when it is combined with other chlorinated hydrocarbon insecticides.

Chlordane is absorbed into the body from the gastrointestinal tract, respiratory tract, and skin. Information is lacking on the comparative absorptive rates between chlordane and the other chlorinated hydrocarbon insecticides by these various routes of entrance. It would seem, however, that the volatile and liquid nature of the chemical would lend itself to a more rapid and greater penetrability of the body barriers than many other synthetic insecticides belonging to the chlorinated class. Chlordane may be absorbed by the body from any type of formulation, although the physiochemical characteristics of the solvents and diluents present may influence the rate at which this occurs.

Little is known about the distribution of chlordane in tissues, its rate of disappearance, or the susceptibility to chlordane of various animal species. There are indications that chlordane or a chlordane-like compound is stored in some form, especially in fat. It seems to disappear fairly rapidly when administration of the insecticide is discontinued. Acidic chlorine-containing degradation products, which are water-soluble at pH 8.6 or higher, have been isolated from rabbit urine, suggesting that this may be the mechanism for detoxification of chlordane in the animal body. It has also been observed that a substance, which is toxic to the suckling young of the species, is secreted in the milk of lactating rats fed a diet containing 150 ppm of chlordane. Young animals have been found to be more susceptible to chlordane than adults, and it is slightly more toxic for female rats than for males. Individual susceptibility to the compound varies greatly. Other comparisons within and among animal species have not been reported.

TOXICITY

Chlordane is one of the more hazardous of the chlorinated hydrocarbon insecticides. It is a lipophilic liquid that is readily absorbed by the skin, alone, as well as in the presence of solvents. It has a low but appreciable vapor pressure and definite residual properties. Lastly, and perhaps of greatest significance, is the fact that the technical preparation is still an uncharacterized mixture of chlorinated hydrocarbons whose toxic properties and metabolic fates are poorly understood. Although recent evidence supports the contention that current production provides a more uniform mixture whose toxicity to experimental animals is less than that reported in earlier studies, no satisfactory analytical method exists for precise identification and estimation of the contents of the commercial mixture.

Oral Toxicity.—Until recently, the oral dose of chlordane that is fatal to humans was not known. A reported suicide, presented in the statement accompanying this review, indicates that about 100 mg. per kilogram of body weight of the technical mixture has killed an adult. Other reports of fatal injury exist, but determination of the lethal influence of chlordane was complicated by the presence of other pharmacologically active agents.

The chronic oral toxic dose of chlordane for humans is not known. In long-term feeding tests, chlordane was found to be significantly more toxic to rats than chlorophenothane, although on an acute basis it has been found to vary from approximately one-half to twice the toxicity of chlorophenothane. The estimated chronic oral toxicity of chlordane ranges from two to four times that of chlorophenothane. Unfortunately, these estimates have even less than their usual meaning in terms of amounts that may be harmful to humans because of the uncertain composition of the technical mixture used in the various studies on which these estimates were based.

Skin Toxicity.—After dermal application chlordane is more toxic than chlorophenothane because it is readily absorbed through the unbroken skin. Since it is an oily liquid by nature, even dry formulations do not prevent cutaneous absorption. Particularly significant is the relatively high toxicity of preparations of chlordane in the form of wettable powders. This type of formulation is usually assumed to be less readily absorbed than solutions containing solvents. The hazards from repeated skin exposure to chlordane are sufficiently great to warrant cautions against its use in insecticidal waxes, polishes, and similar preparations that might contact the skin frequently. Its rapid absorption through the skin and greater toxicity after repeated application justify these limitations in use.

The skin irritating properties of technical chlordane mixture are said to have been decreased with the reduction in the amount of unreacted chemical intermediates in the mixture. Irritation of skin and mucous membranes continues to be reported, however, as evidenced by the case reports. If petroleum distillate solvents are present, they may contribute to the irritating properties but not necessarily to the sensitizing properties of the technical product.

Although superior to chlorophenothane in action, chlordane was found to be too toxic for formulation into louse powders to be used in the armed forces. For the same reason it is the least acceptable of the several insecticides used as dips for farm animals. At ordinary concentrations and frequencies of application, chlordane does not produce signs of acute poisoning; however, experience has shown that it has a narrow margin of safety in livestock pest control. Increased uniformity in production of the technical mixture is expected to improve the safety factor.

Inhalation Toxicity.—Little is known about the inhalation toxicity of chlordane. On a comparative basis the possibilities for poisoning by this avenue of entrance into the body are believed to be greater with technical chlordane than with chlorophenothane formulations because of the physicochemical characteristics of the former substance. Certain suggestive findings derived from the use of chlordane and closely related chemicals seem to support this contention. The technical mixture is a slightly volatile liquid with significant residual characteristics. Fumes are given off over an extended period of time and unless readily dissipated offer a distinct danger to persons who are exposed. Available reports of human injury by chlordane vapors or fumes are controversial, although clinically verified cases of poisoning from combined skin and respiratory exposures to closely related chemicals that are also present in technical chlordane have been recorded.

Adverse effects were reported in laboratory animals and birds whose living quarters had been treated with chlordane formulations in spite of subsequent treatment with strong alkaline detergents and a thorough airing. Mice also were reported to have manifested a loss of activity and muscular coordination after breathing a low concentration of chlordane vapors for a few weeks. Weight gains and appetite were normal during this period, but liver damage became evident after six weeks of exposure. One-half the mice died in periods varying up to the 15th week, and all were dead in 16 weeks. Mice that breathed air saturated with chlordane lost all coordination and became blind in a few hours. All died in four days when exposed continuously to the vapor.

These injuries have been attributed to certain impurities present in earlier batches of the technical mixture. Current chlordane production is stated to have reduced at least one of these elements, hexachlorocyclopentadiene, to a minimum as evidenced by subsequent animal experiments and by the experience of one man who voluntarily exposed himself to a chlordane fog for a short interval, biweekly, for three months. These reports should not be interpreted as indicating that the vapor hazard is no longer of any consequence.

Pathology.—The pathological findings in the two fatalities attributed to chlordane described in the accompanying report of the Committee are generally similar to those observed in experimental animals and livestock who received acute lethal doses of the chemical. Pulmonary edema and gastrointestinal irritation dominate the pathological picture of acute poisoning in experimental animals, whereas generalized congestion, edema, and hemorrhage into various organs were reported in human cases. Irritation and chemical burns of the alimentary tract were also noted in the person who ingested a fatal dose of chlordane.

Postmortem findings in chronic chlordane poisoning are equally nonspecific. In addition to signs of severe vascular injury, parenchymatous degenerative changes in the liver and kidney have been observed. These are characteristics of long-term toxic exposure to chlorinated hydrocarbon compounds. The liver is the most sensitive organ and reveals the greatest degree of cell alteration. At low levels of exposure to chlordane, changes in liver cells cannot be correlated with changes in physiology. The question of whether these anatomic modifications represent functional impairment is a problem to which present scientific knowledge has no answer.

Symptoms.—The symptoms of acute chlordane intoxication are similar to those observed in poisoning by chlorophenothane and other chlorinated hydrocarbon insecticides. Irritability, salivation, labored respiration, muscle tremors, convulsions, and death with or without an immediately preceding period of deep depression is the classical pattern of poisoning in experimental animals. These symptoms, which are referable to the central nervous system, have all been observed in humans. Nausea, vomiting, diarrhea, and abdominal pain have been reported to follow ingestion of toxic doses. Blurred vision, cough, ataxia, confusion, delirium, and mania are further symptoms noted after inhalation and skin absorption of poisonous amounts of chlordane.

The accentuation or predominance of any particular symptom or group of symptoms depends primarily on the severity of the poisoning and to a lesser extent on the type of exposure. The onset of symptoms and the course of poisoning are influenced both by the mode of entrance into the animal body and by the solvent vehicle or other additives present in the formulation. Generally speaking, acute signs of poisoning usually appear within 45 minutes after ingestion. Death may occur within 24 hours; it is frequent between the 48th and 96th hours, but it may be delayed many days following a single oral toxic dose.

Chronic chlordane poisoning may be manifested by disturbances of the central nervous system; it particularly affects the optic nerve. Moderate skin irritation, liver damage, and inanition also have been observed in experimental animals. Albuminuria develops shortly before death and in some instances has been the only objective evidence of cumulative toxicity. Unfortunately, the late appearance of this symptom precludes its use as a diagnostic sign in the determination of incipient poisoning resulting from prolonged exposure to chlordane.

Treatment.—The management of chlordane poisoning, like that for intoxication from other of the chlorinated hydrocaron insecticides, depends on the use of symptomatic measures; hat is, the removal of the poison from the skin or stomach ollowed by a saline purge and sedative therapy. In case of ccidental skin contact, the contaminated areas should be imnediately washed with soap and water to prevent or reduce bsorption. Dermatological therapy should be instituted for ontrol of inflammatory or other irritant skin conditions. If hlordane is ingested, gastric lavage followed by the administration of epsom salts or other saline cathartics is recommended. ince milk, oil purgatives, and other fatty or oily demulcents nd evacuants facilitate absorption of the toxicant, they should e avoided. Intravenous administration of secobarbital sodium, iopental sodium, or other short-acting barbiturates is sugested for the rapid treatment of the extremes of central nervous ystem stimulation in acute poisoning. Phenobarbital sodium is dvised for more prolonged sedation and for treatment of the ore moderate symptoms of overstimulation. When renal or epatic damage is suspected, appropriate treatment should be stituted.

CLINICAL EXPERIENCE

Several deaths have occurred after exposure to heavy conntrations of chlordane. The fatalities reported to the Comittee are listed in the accompanying table. Too often, hower, published reports of poisoning are merely representative many injuries that, for a variety of reasons, are unrecorded. would therefore be misleading to make comparisons or otherise generalize on the safety of chlordane when full facts on toxic character and actual safety record are poorly underood.

With the exception of the suicide that is described in detail the accompanying report, the several tabulated deaths ributed to chlordane have all been complicated by the presce of other agents with pharmacological activity. In the dustrial accident, the diagnosis of the cause of death was comcated by the presence of a related compound, chlorophenoine, and emulsifying agents that facilitated absorption of both lordane and chlorophenothane. While it cannot be stated unuivocally that chlorophenothane was without influence, chlorne is believed to be the responsible agent because of its greater n toxicity after single exposures. In another recorded fatality, onic alcoholism made the diagnosis difficult. Although the intion of chlordane solution was believed to be the precipitat and influencing factor in death, the presence of severe liver nage sufficiently incapacitated the victim so that normally lethal doses of chlordane were fatal. Liver damage may also ve been a contributing factor in the undiagnosed death of a ient with a history of gross skin exposure to a chlordane ay.

57-year-old vagrant, a known chronic alcoholic, was treated for lice r to transfer to another jail. The disinfestation consisted of spraying prisoner with nearly a pint of a fly spray containing 2% chlordane a petroleum distillate base. The incident occurred in the summer and sumably the man wore little clothing. He suffered from a chronic, ping, and generalized eczema. Shortly after the spraying he collapsed. er 45 minutes marked by muscle twitching and convulsive movements, prisoner died. Severe liver degeneration compatible with chronic holism was found on autopsy. No chlordane was discovered in ues, and no cause of death was assigned at autopsy.

The recorded nonfatal systemic poisonings attributed to ordane were largely the result of carelessness in the handling d storage of the commercial mixture. Improper storage in a dicine cabinet and in a drinking glass and the spraying of an ant by her 3-year-old brother accounted for three misadvenes with the product. A lack of informative labeling on locally tributed preparations enhanced the seriousness of poisoning another case of accidental ingestion. Excessive inhalation and n contact of chlordane during application by a week-end rdener, park employee, pest control operator, and three agriltural workers accounted for symptoms of poisoning in six ditional cases of nonfatal injury. Local and systemic sensiity reactions have also been attributed to chlordane.

A number of cases of contact dermatitis have been reported nong exterminators and employees of pest control firms with tle or no previous history of allergy or skin trouble. In several stances patch tests confirmed the relationship, and in all instances removal from exposure to chlordane improved the skin condition. Examination of workers in two industrial plants manufacturing chlordane, however, did not reveal any evidence of injury. Systemic reactions with a possible allergic basis associated with chlordane exposure have been infrequently reported.

A fatal case of aplastic anemia in a patient with a history of exposure to chlordane and toxaphene has been reported to the Committee. The patient, a woman aged 40, with no history of allergy, had a primary refractory anemia of undiagnosed etiology. Her history was essentially negative except for occasional exposure to chlordane, toxaphene, and headache pills (aspirin and a proprietary mixture containing aspirin, acetophenetidin, and caffeine). Exposure to chlordane and toxaphene resulted from the picking and handling of cotton balls from a field previously treated with these insecticides. After her illness began, additional drugs were taken including penicillin, unspecified sulfonamides, "appetite reducers," and estrogens. After a protracted illness of two and one-half years, the patient died of aplastic anemia with marked hemorrhage as the terminal event.

A second fatality involving hypoplastic anemia in a previously healthy college student after use of a water-based chlordane spray is more suggestive. The patient had repeatedly sprayed for ants around the baseboard of his study and bathroom. On these occasions, he is reported to have remained in the unventilated room to study. After an illness of 13 months, the patient died from extensive internal hemorrhages. In both cases, there was a history of exposure to common drugs such as aspirin and sulfonamide.

FATAL CHLORDANE POISONING

Vincent J. Derbes, M.D.
J. H. Dent, M.D.
W. W. Forrest, M.D.
and
M. F. Johnson, M.D., New Orleans

This report describes two human fatalities from chlordane poisoning. One of these was caused by absorption of accidentally spilled chlordane; in the second case the patient swallowed chlordane deliberately, with suicidal intent. These are the first examples of fatal chlordane poisoning in human beings that have been reported in detail. Since chlordane is used so widely as a domestic and agricultural insecticide, it seems desirable to report the findings in these cases as a general warning.

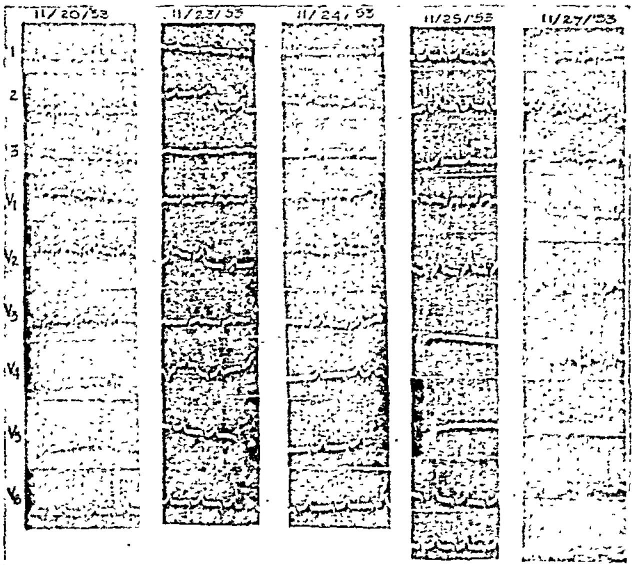

Fig. 1.—Electrocardiograms in case 2. The depressed S-T segments and T waves changes of Nov. 27, 1953, are in accord with the postmortem findings of myocarditis. They also suggest or are compatible with electrolyte disturbances.

From the Department of Medicine (Drs. Derbes and Johnson) and the Department of Pathology (Drs. Dent and Forrest), Tulane University School of Medicine, and from the Charity Hospital of Louisiana.

Dr. Wayland J. Hayes Jr. and Mr. Bernard E. Conley gave criticisms and suggestions during the preparation of this report.

REPORT OF CASES

Case 1.—A 23-year-old woman, who had worked with insecticides for perhaps two years and whose hands had been in contact with this material, on Oct. 21, 1949, spilled an unknown amount of a suspension consisting of 25 lb. of chlordane, 26 lb. of chlorophenothane (DDT), 39 lb. of velsicol AR 50, and 10 lb. of triton X-100 on the front of her clothing. About 40 minutes later she became confused and rather suddenly began having generalized convulsions. Attendants attempted to wash the material off her abdomen and thighs, but the contaminated clothing was not removed. She was promptly sent to a doctor's office by ambulance, but on arrival she was dead. There was no evidence that she had shown previous symptoms of drug intoxication, even though she had handled many of the chlorinated hydrocarbons during the two years.

Table 1.—*Autopsy Findings in Case 2 Performed Twenty-Four Hours After Post Mortem*

External Examination	
Left pupil	slightly irregular in shape
Left conjunctiva	minute hemorrhagic area laterally
Gingivae	shallow areas of ulceration covered with a black crust
Lips Buccal mucosa Hard palate	surgical ulcers
Sacrum	shallow decubitus ulcer, 4 × 4 cm.
Neck Organs	
Epiglottis	ulceration on epithelium
Larynx	contained dirty, tenacious, brown fluid resembling aspirated stomach contents
Thoracic Cavity	
Lungs	weight, 1,350 gm.; pleura of both lower lobes coated with thin fibrinous exudate; extensive confluent bronchopneumonia in both lower lobes and left upper lobe; cut surface friable, with a dirty brown fluid exudate
Pericardial Cavity	
Heart (fig. 3*A*)	weight, 300 gm.; right ventricle 0.3 cm. thick, left ventricle 1.2 cm. thick; both dilated; myocardium flabby; coronary arteries patent
Cranial Cavity	
Brain (fig. 3*C*)	weight, 1,170 gm.; no significant gross abnormalities
Peritoneal Cavity	
Liver	weight, 1,450 gm.; no gross abnormalities except for scattered areas of congestion
Spleen	weight, 140 gm.; cut surface soft; malpighian corpuscles indistinct
Kidneys (fig. 3*B*)	weight, 300 gm.; pale tan, flabby; capsules stripped revealed smooth surfaces; cut section of cortex, pale and swollen; pyramids congested and red
Urinary bladder	edema; scattered areas of hemorrhage in mucosa
Endometrium	hemorrhagic in areas
Vagina	superficial ulceration in mucosa
Cervix	mucopurulent exudate in external os
Pancreas Adrenals Stomach Intestines Fallopian Tubes Ovaries Myometrium	not remarkable

At autopsy it was found that the lungs and kidneys were congested and hemorrhagic; the stomach mucosae showed congestion. When the gross specimens were reviewed, no characteristic chemical odor was noted. The kidneys and lungs were congested; the liver was pale, but no lesions were noted in the heart, spleen, or stomach. The brain showed congestion, scattered petechiae, and edema; there was flattening of the gyri and numerous petechiae were scattered throughout. When the microscopic sections were reviewed, no pathognomonic lesions were found. Edema of the lungs, generalized congestion, and cloudy swelling were observed as in experimental animals poisoned the chlorinated hydrocarbons. The patient's symptoms and autopsy lesions were similar to those in animals poisoned chlorinated insecticides.

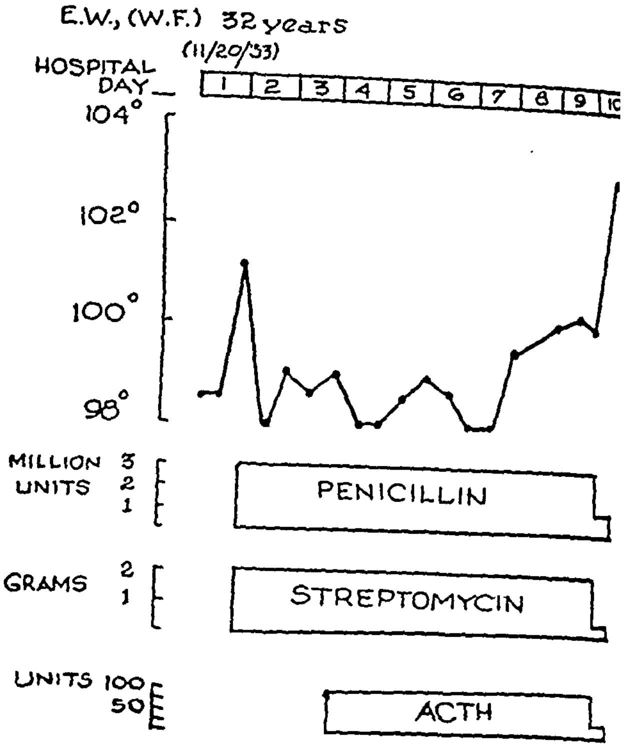

Fig. 2.—Summary of clinical course in case 2.

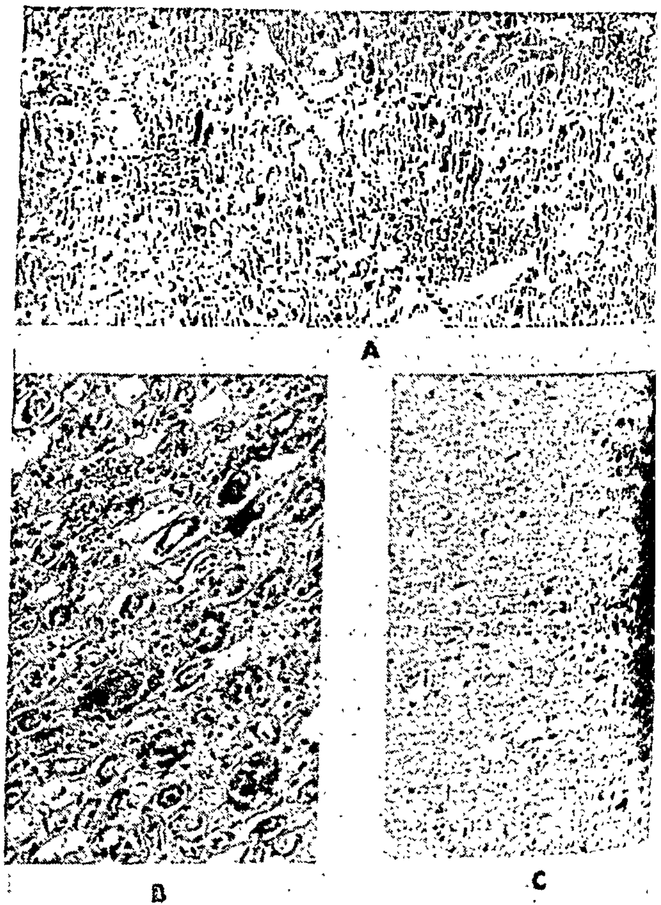

Fig. 3.—*A*, myocardium of patient in case 2 in which congestion a petechiae may be seen. *B*, kidneys of patient in case 2 showing casts in the distal collecting tubules. *C*, brain of patient in case 2 show focal area of gliosis within the basal ganglions. The neuronal ch are post mortem.

Case 2.—A 32-year-old, chronically depressed white wid had attempted suicide twice in 1944, first using roach poi and then a barbiturate. *On Nov. 19, 1953*, about 8 p. m., s half filled an 8 oz. glass with toxichlor dust, which contains 5% chlordane and related chemicals and 95% talc. She added water and swallowed the mixture.

About 10:30 p. m. she began to vomit and continued to vomit throughout the night. After about three hours the vomitus became blood streaked. Several hours later she became hoarse and a dry cough developed. On the afternoon of Nov. 20 she s admitted to a hospital. She was haggard, with a wild, wide- d look, and was agitated and restless. Apprehension was table. The voice was hoarse and nasal. She moved her mouth le or none when speaking because of buccal pain. Tempera- e was 99.8 F (rectal); pulse rate 88 beats per minute; respira- n rate 20 per minute; blood pressure 140/92 mm. Hg. There s lateral nystagmus; diopter cupping of the optic disks was sent. Old caked blood was seen on the teeth and about the s; gingivitis was intense, a gray exudate covered the gums, ccal mucosa, uvula, tonsillar pillars, and pharynx; the tongue s quite red. Breathing was noisy; medium and coarse moist les were heard throughout both lungs, but there was no dull- ss or altered breath sounds. The heart and abdomen were rmal. Except for the afore-mentioned findings the neurologi- l examination was normal. The electrocardiogram revealed rate of 118 beats per minute; the P-R interval was 0.11 seconds, e QRS time was 0.08 second; T waves were diphasic (fig. 1).

She had been completely anuric since admission to the hos- tal. An infusion of 750 cc. of glucose-saline was given. pproximately 20 cc. of urine was collected from the indwell- g catheter. She was given nasal oxygen, penicillin (3 million nits daily), and streptomycin (2 gm. daily). Cough and expec- ration occurred and cyanosis appeared.

On Nov. 21 increasingly severe pain in the mouth, throat, nd epigastrium required meperidine hydrochloride for relief. he breath was foul. Sputum became so tenacious that suction as required. The blood pressure fell to 86/48 mm. Hg, but ressure rose to 100/60 mm. Hg after administration of levarte- nol bitartrate. On Nov. 22 corticotropin therapy was begun a dosage of 100 units daily, given intramuscularly. Pain in he abdomen and throat continued and apprehension was in- ense. A small, dark brown, liquid stool containing occult blood vas passed. On Nov. 23 palmar erythema, which had been quivocally present the day before, became obvious. Amobarbi- al sodium, 0.25 gm., was given intramuscularly for restlessness. On Nov. 24 speech was incoherent and irrational. On Nov. 26 she vomited a dark oily liquid, and diarrhea occurred. A roentgenogram showed a diffuse bronchopneumonia. She became increasingly agitated. Only partial sedation was obtained after administration of 30 cc. of paraldehyde on Nov. 27. On Nov. 28 she continually moaned, cried, and shouted. In spite of continuous administration of oxygen, cyanosis was present. The breath had a peculiar, unpleasant odor. The white blood cell count was 78,000 per cubic millimeter. Blood pressure fell to 50/0 mm. Hg at 10 a. m., and levarterenol was added to a 500 cc. transfusion, causing a temporary improvement. About midnight muscle twitching was noted. At 2:15 a. m. on Nov. 29 generalized tonic and clonic convulsions lasted 10 minutes. Convulsions of shorter duration continued until death at 8:30 a. m., approximately 228 hours (nine and one-half days) after ingestion of the chlordane. Laboratory data and autopsy findings are given in tables 1, 2, and 3; a summary of the clinical course is given in figure 2.

SUMMARY

Two fatalities presumably caused by chlordane are reported. The first patient became confused, started having convulsions, and died within a few minutes after an accident in which a suspension of chlordane was spilled on her dress. Nonspecific pathological changes were found in the brain, lungs, and kidneys. The second patient died nine and one-half days after swallowing 6 gm. of chlordane (104 mg. per kilogram of body weight). Clinical features included chemical burns of the mouth, a severe hemorrhagic gastritis. shock, anuria, convulsions, and death. The pathological features were cerebral congestion and edema, lower nephron nephrosis, confluent bronchopneumonia, chemical burns of the mouth, and uremia.

CHEMICAL LABORATORY

DECAFFEINATED COFFEE

The article entitled "Xanthines, Tannins, and Sodium in Coffee, Tea, and Cocoa," which appeared in THE JOURNAL, July 23, 1955, page 1030, reported results for caffeine content of beverages based on a gravimetric procedure. This report stated, among other things, "Advertising that makes claims implying almost total removal of caffeine in decaffeinated coffees must be viewed with skepticism." Further review indicates that the analytical procedure used can lead to inaccurate results in the case of decaffeinated coffees, therefore, the conclusions of the July 23 report of the Chemical Laboratory may have been premature. The Chemical Laboratory is, however, undertaking a further investigation of decaffeinated coffees utilizing a different method of analysis. Until completion of this investigation, any conclusions based on the laboratory's earlier findings relating to decaffeinated coffees should be held in abeyance.

PREVENTING ACCIDENTAL POISONING

GUEST EDITORIAL

Irvin Kerlan, M.D.

In 1951 accidental poisoning by solid and liquid substances caused 1,497 deaths, of which 411 were in children under 5 years of age. These statistics do not reveal the full picture. They do not point out the staggering number of nonfatal poisonings, which is estimated to be 100 to 150 times the number of fatalities. The public must be awakened to the hazards of misuse of drugs and other household chemicals in a continuing effort to prevent accidents in the home. Poisonings by common household items such as bleaches; cleaning fluid; furniture polish; lye; kerosene; rat and insect poisons; weed killers; medicines including aspirin, methyl salicylate, and boric acid; and cosmetics and toilet goods are particularly tragic since they are preventable. Too often parents have permitted accidental poisoning of their children through carelessness or lack of information. With thought, instruction, and effort they can reduce poisoning risks.

Wider community participation in accident prevention programs can be readily achieved. There is a broad range of possibilities for telling the child-safety story. Especially responsive to furthering the poisoning prevention activities would be youth groups, parent-teacher organizations, women's clubs, and home economists. Among the young people's groups should be mentioned the Boy Scouts, Girl Scouts, Campfire Girls, 4-H Club, and church groups. National health groups are already actively concerned with reducing the accidental poisoning hazards; they include the Red Cross, National Safety Council, medical societies, health departments, and large insurance companies. The Food and Drug Administration through its responsibilities under the Federal Food, Drug, and Cosmetic Act and the Caustic Poisons Law has been close to the problem and has participated in its correction through legal and educational means.

The number of interested groups can be extended to provide protection through community participation in continued accident prevention programs. Local and national public educational mediums such as newspapers, radio, television, films, public speeches, displays, posters, and readily available information in pamphlets, booklets, and leaflets should be employed recurrently to tell this safety story. Each community should develop its own program, depending on local resources.

The number of potentially toxic substances in the home that may be accidentally swallowed is huge and is increasing daily. Recent advances in the production of new chemicals and their ready availability in the home through advanced manufacturing processes, advertising, and marketing increase the need to keep abreast of these new developments, their potentiality for poisoning, and adequate treatment in case of misuse or accidental ingestion. The physician needs much background to be kept informed of the toxic chemicals contained in all of the chemical agents found around the home and the most effective treatment when a mishap may result in poisoning. These needs have led to formation of a Committee on Toxicology by the American Medical Association and development of poisoning control centers.

The American Medical Association through its recently formed Committee on Toxicology is devoting special attention to correcting the accidental misuse of chemical products found in and around the home. The Committee has advanced a five point program to (1) encourage informative labeling and safe packaging, (2) stimulate laboratory and clinical research for antidotes, (3) standardize technical nomenclature, (4) develop criteria for evaluating hazardous substances, and (5) sponsor a sustained educational program. The results of these studies are periodically reported to the profession in THE JOURNAL and other publications that are concerned with health matters. Poisoning control centers have been formed under the sponsorship of local health departments and pediatric societies. Through these centers much already has been learned about the types of substances that are accidentally ingested. Moreover, opportunity has been provided through follow-up home visits to acquaint parents with home safety hints.

CHLOROPHENOTHANE (DDT)—A BLESSING OR A MENACE?

Chlorophenothane (DDT) is produced in greater tonnage than any other insecticide. Although it is cumulative in human adipose tissue, it acts primarily on the central nervous system, producing hyperexcitation, generalized tremors, spastic or flaccid paralysis, and convulsions.[1] Like many other chemicals recently introduced on a large scale, it has been widely used with little regard for possible long-term effects on the human body or effect on beneficial forms of life, and for this reason some observers [2] have sounded a note of alarm. It may be absorbed through the intact skin, respiratory system.

---

[1] Pharmacologic and Toxicologic Aspects of DDT (Chlorophenothane U. S. P.), report of Council on Pharmacy and Chemistry, J. A. M. A. **145**: 728-732 (March 10) 1951.

[2] Biskind, M. S.: Public Health Aspects of the New Insecticides, Am. J. Digest. Dis. **20**: 331-341 (Nov.) 1953.

r gastrointestinal tract. Absorption through the skin s negligible unless the skin is very oily or the insecticide s in an oily solution. In the latter case some of the reulting cutaneous irritation may be due to the solvent sed. The chief hazard to the skin is in handling conntrated solutions in the process of diluting them to e strength recommended for spraying. Hayes [3] states at no authenticated case of systemic poisoning followg even heavy dermal or respiratory exposure has been ported. On the other hand, the inert diluents used in e wettable powder are respiratory irritants. It may be fely said, however, that from the standpoint of respirary exposure dusting and aerosol operations are not zardous under ordinary conditions.[1]

For the average person then the greatest potential hazd would result from constant ingestion of small nounts of chlorophenothane that has been sprayed on e fruits and vegetables consumed or that has been desited in the adipose tissue of domestic animals used meat. When chlorophenothane is ingested we must ain consider the toxicity of the solvent and the fact at a digestible solvent increases the rate of absorption the insecticide. Although it cannot be denied that the erage meal consumed in this country contains about 31 ppm of chlorophenothane (dry weight) a person ely ingests more than 0.0026 mg. per kilogram of dy weight per day. Human volunteers have ingested much as 0.5 mg. per kilogram of body weight per y for prolonged periods without injury,[3] and the fatal l dose for man is about 0.5 gm. per kilogram of body ight. Hsieh [4] reported the accidental introduction of % wettable chlorophenothane powder into flour used make dumplings, each of which contained about 286 of chlorophenothane. Eleven members of a family one or more dumplings, and three reported no sympns, while the rest complained of sweats, tremors, miting, headache, and/or convulsions. They were en saline enemas and magnesium sulfate by mouth, d all were well within two days.

Chlorophenothane is detoxified in the liver and exted slowly in the urine over a period of two weeks more. Hayes [3] states that the degree of exposure n be measured quantitatively by determining the retion of the acetic acid derivative of chlorophenone in the urine. The margin of safety is wide because en a large dose is ingested much of it is eliminated by miting, and of that which remains relatively little is sorbed.

When a large dose of chlorophenothane is known to ve been ingested, the patient should be treated with vage followed by a saline purge, and fats should be oided until the danger is over. Anyone whose occution brings him into contact with powdered chloroenothane should wear a respirator, or, if he must ndle chlorophenothane in an oily solution, he should ear impervious gloves and other protective clothing. bout the house, chlorophenothane should never be kept in the medicine chest, and, if the kitchen must be sprayed, all food, utensils, and table tops should be covered. Toys, cribs, nurseries, and sickrooms should not be sprayed.[1]

In the light of recent reports, Biskind's [2] claim that the facts regarding chlorophenothane have been concealed, suppressed, denied, and distorted no longer holds true. Too many persons are willing or eager to attribute an increase in certain illnesses or an otherwise unexplained death to an exposure to some new chemical hazard without matching the patient's signs and symptoms with the known effects of poisonous doses of the chemical or determining the degree of the patient's exposure.[5] Under the current administrative setup, the Department of Agriculture discusses the hazards of handling all new insecticides with the Public Health Service and requests the Food and Drug Administration to evaluate the hazards resulting directly or indirectly from residues on foods.[6] In the case of chlorophenothane, it is safe under ordinary conditions of legitimate use and definitely safer than such insecticides as arsenic, nicotine, and sodium fluoride.

COBALT AND THYROID FUNCTION

A communication describing the enlargement of the thyroid gland during the administration of a cobalt salt was recently published in The Journal.[1] In effect it suggested the need for caution if this cobalt is used, even though a number of favorable reports on its use in anemia have appeared in the literature. Almost as soon as The Journal communication appeared questions were raised concerning its clinical significance. As a result four papers were submitted for publication, and these appear elsewhere in this issue (see pages 1347-1357). They embrace work done on lower animals and observations on human beings. Normally experiments on lower animals are better suited to publication in a more specialized periodical, but in this instance the four articles complement each other in a way that encourages their publication as a group, and they are offered without comment to those readers who are interested in the use of cobalt. Undoubtedly, as often is the case in therapeutics, a difference of opinion has arisen. More work may be in order, or sufficient data may be available now. The Journal is merely presenting recently acquired data, leaving to the reader the privilege of drawing his own conclusions.

ORGANIZATION SECTION

SOCIAL SECURITY

In the July, 1955, issue of the World Medical Journal *is a statement on social security by Dr. Louis H. Bauer, secretary general of the World Medical Association. This subject is currently of much interest to doctors in the United States, and Dr. Bauer's statement is reproduced for this reason.*—Ed.

In the field of social security the same struggle seems to go on and on. Governments and social security bodies are on one side and the medical profession on the other.

There is, of course, no more popular issue for politicians than the subject of medical care. It has an emotional appeal that attracts votes. It is easy for politicians to promise the world surrounded by a fence of gold, particularly when they are promising the delivery of the services of another group. That they cannot deliver on their promises does not bother them at all. They can always (and usually do) blame the doctors for any shortcomings of their systems. If the politicians expand benefits and the costs go up, then the doctors are writing too many prescriptions or they are using too expensive drugs, or they are making too many visits. That the broadening of coverage and expansion of benefits cost money never seems to occur to the politicians or if it does they ignore it. It is much easier to blame the doctors and cut expenses through them.

The result is that the directors of these systems strive constantly towards greater control over the medical profession. One only has to review the history of social security and government medicine to realize that the eventual aim of these people is to make the doctors full-time salaried servants of the state or the social security bodies. If they can accomplish this, then they can dictate to the medical profession on every phase of the practice of medicine. They can tell doctors *where* they *must* practice. They can tell them *how* they must practice, that is, how many visits they will make, how many people they will care for, how they will treat them, what they will be paid, etc.

This is no wild prognostication on my part. Several individuals, high in the social security hierarchy, have publicly expressed every one of these aims.

Most of these people are unwilling to listen to suggestion. Everything must be done according to their own warped philosophy.

Doctors wish their patients to have good medical care. They will deliver it if they are given the opportunity to do so. It seems to astound the social security "bosses" that the medical profession feels it is better qualified than any laymen to determine the medical needs of their patients, and how and where they should be treated.

Doctors feel that the patient has an inalienable right to choose his own doctor. Doctors know that the faith of the patient in his doctor is an important asset in treatment. Patients have little confidence in "assembly line" treatment or in a doctor who treats them merely as case numbers and has no time to listen to their stories.

From time immemorial doctors have treated patients as individuals and if they were unable to pay, they have treated them free. Mass treatment given according to hard and fast regulations has no place in the therapeutics of the conscientious doctor. No two cases of the same disease are necessarily treated alike. When laymen, however, exercise control they want everyone treated by a strict formula. They ignore the doctor-patient relationship, even scoff at it as mere sentimentality and of no importance.

It is high time that certain social security planners woke up to the fact that members of the medical profession will refuse to become slaves to a system that is contrary to all their training, to the traditions of their profession, and to philosophy of a free state.

If the social security hierarchy persists in its arbitrary, domineering attitude they will succeed in discouraging persons endowed with ambition and intelligence from entering the medical profession. There is little incentive for a man to enter a profession if he is to receive no more recognition for doing good work than does his colleague for doing poor work; or if his income is to depend entirely upon length of service and political influence; or if he is to be hedged around with arbitrary and often senseless rules and regulations, the infraction of which will result in his being subject to disciplinary action by others than his peers.

All this will result not only in an inferior type of individual entering medicine, but the public will receive an inferior grade of medical care. Research will disappear and progress in medical science will cease.

Advice with reference to a system of medical care is rarely sought by governments and never by social security fanatics from those best qualified to give it. They almost universally ignore the organized medical profession.

The people want and should have the best medical care and the doctors want to give it to them. They have little chance of getting it, however, until governments and social security autocrats come down out of their ivory towers and follow the precept so emphatically stated by the Right Honorable Sir Earle Page, Health Minister of Australia. He said, in substance, that it is impossible to make any system work which does not enlist the cooperation of those who have to carry it out.

Social security has occupied a great part of the attention of delegates to every general assembly. The discussion has not bee as profitable as it might, however, because everyone has endeavored to cover the whole field.

Hence, the Council [of the World Medical Association] recommended that a different approach be adopted at the General Assembly [of the World Medical Association; this be held in September in Vienna]. There will be a general t for discussion. This will be entitled,

"A Realistic Approach to the Economic and Political Asp of Social Security."

A paper on this subject will be presented by the chairm of the social security committee. Then the subject will thrown open to discussion, which will be limited to the foll ing aspects:

1. Cost of Medical Service (Administrative Costs)
2. Cost of Medicaments
3. Cost of Hospitalization
4. Social Security Cash Benefits

The Council is of the opinion that by such an approach, real contribution will result. There certainly should be sufficie facts brought out to demonstrate who or what is responsi for these costs constantly increasing. In my humble opinion will *not* be the medical profession which is found guilty.

It has been suggested to the social security planners ma times before and by many people that housing, clothing, a nutrition have a great influence on the health of the peop Were the social welfare group to concentrate on these fac there would be far less need for medical care. So, too, envir mental sanitation, protection of food, milk, and water su plies, eradication of disease bearing insects are public hea factors that are properly the function of government. If gove ment would spend their time, money, and energy on some of these, they would be doing a great deal for the people, and again making the need for medical care less prevalent.

Such a course, would not only redound to the benefit of the people, but in the long run would be economical. Furthermore, it would be sensible. So, it is too much to expect, particularly as it would have less "vote appeal."

EXCERPTS FROM MINUTES OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS, JUNE 3-6, 1955

The Committee on Essentials of the Council has recommended that the section on "Aims and Objectives of a Training Program" in the "Essentials of an Approved Internship" and the "Essentials of Approved Residencies and Fellowships," be revised to incorporate the following statement:

"Throughout the internship (residency) program, time and thought should be devoted to the inculcation of the concept of medicine as an art and as a calling, the primary purpose of which is the care and treatment of the patient as an individual in addition to the emphasis on scientific and objective studies of disease. In achieving this end, stress should be laid on understanding and evaluating the patient's family relations, his economic and social status and his position in the community. It is only by grasping the importance of the patient as a composite entity that the physician can attain the fullest mastery of his profession. Those charged with the responsibility of training younger physicians must teach them by precept and example, the human as well as the scientific aspects of the lofty discipline of medicine."

The Essentials Committee also recommended that both of the publications indicated above include the following statement in an appropriate place:

"To avoid ambiguity and lack of definiteness, it is recommended that the Standard Nomenclature of Diseases and Operations be used by the medical staff to record the clinical diagnoses of patients."

During the academic year 1954-1955, the liaison survey visits with representation from the Association of American Medical Colleges as well as from the Council on Medical Education and Hospitals were made to the following medical schools in the United States and Canada:

Indiana University
University of Toronto
George Washington University
University of Louisville
St. Louis University
Emory University
Duke University
Western Reserve University
University of Southern California
University of Florida
University of California at Los Angeles
University of California at Berkeley and San Francisco
Seton Hall University
University of Montreal
New York Medical College
Albert Einstein College of Medicine
University of Ottawa
University of Virginia

Howard University was also visited by representation of the Liaison Committee in cooperation with the Middle States Commission on Institutions of Higher Education.

Provisional schedules have been worked out for the medical school survey visits during both 1955-1956 and 1956-1957. During 1955-1956 liaison survey visits will include State University of New York Upstate Medical Center at Syracuse, University of Miami, University of Maryland, Tulane University, Jefferson Medical College, University of Nebraska, Cornell University Medical College, Dartmouth Medical School, McGill University Faculty of Medicine, Queens University Faculty of Medicine, University of Vermont, and University of Alberta Medical Faculty.

At the present time, there are 16 residency review committees in active operation. These committees consist of specialty board representatives with Council representatives who evaluate and recommend regarding the residency training programs submitted for their consideration. Residency review committees of this type have not yet been established with the specialty boards in obstetrics and gynecology, anesthesiology, pathology, or thoracic surgery.

It was reported that the proposed program of the Cooperating Committee for the Evaluation of Graduates of Foreign Medical Schools had been studied by the Law Department of the American Medical Association with the regard to the legality of various aspects of the program. The Law Department's brief indicated the necessity for the Committee to review and possibly modify certain aspects of the proposed program in terms of legal implications with the hope that the objectives of the program may be preserved. In line with this suggestion, a special meeting of the Cooperating Committee was called on June 17 for further study. It is apparent that the original program may need considerable modification and that the Cooperating Committee study should be further pursued toward a satisfactory solution.

The Board of Trustees has approved the recommendation of the Council on Medical Education and Hospitals that a permanent position on the Council staff be created for a continuing study in the field of postgraduate medical education. It is hoped that this post may be filled in the course of the relatively near future.

REPORT ON GUIDING PRINCIPLES FOR EVALUATING MANAGEMENT AND UNION HEALTH CENTERS

The following footnote acknowledging the invaluable assistance of several physicians in the preparation of the "Guiding Principles for Evaluating Management and Union Health Centers" was not included in that portion of the "Abstract of Proceedings of the House of Delegates" appearing on pages 835-838 of the July 9, 1955, issue of The Journal. The Council on Industrial Health and the Council on Medical Service wish to call this footnote to the attention of readers of The Journal to indicate that membership on the committee, together with the special consultants, represented a comprehensive cross section of opinion on the essentials for such guiding principles:

"Members of the Committee on Medical Care for Industrial Workers: Drs. W. A. Sawyer, Chairman, Consultant, International Association of Machinists, Rochester, N. Y.; W. F. Draper, Executive Medical Officer, UMWA Welfare & Retirement Fund, Washington, D. C.; A. C. Scott Jr., Member, Council on Medical Service, Temple, Texas; Frank J. Holroyd, A. M. A. delegate, Princeton, W. Va.; M. N. Newquist, Medical Director, The Texas Company, New York, N. Y.; W. Clark Bailey, Vice-President, A. M. A. and Member, Committee on Legislation, A. M. A., Harlan, Ky.; Frederick M. Slobe, Chairman, Committee on Industrial Health, Illinois State Medical Society, Chicago, Ill.; Edwin P. Jordan, Executive Director, American Association of Medical Clinics, Charlottesville, Va.; Consultants—Drs. John Hinman, Council on Medical Education and Hospitals, and Donald A. Dukelow, Bureau of Health Education, both from the A. M. A., Chicago.

"The preparation of the original draft of these Guiding Principles and their further editorial development were carried out in mutual cooperation by Drs. Leo Price and William Hall Lewis Jr. of New York City. Dr. Price has had experience in this field as Medical Director of the Union Health Center, International Ladies Garment Workers Union; he is a former member of the Committee on Medical Care for Industrial Workers (1949-54); he is now a member of the Commission on Medical Care Plans. Dr. Lewis, an independent practicing physician, has been chairman of the Editorial Board of *New York Medicine* and a member of the Committee on Medical Economics of the Medical Society of the County of New York. The Committee is indebted to them in their capacity as special consultants. This report has been a cooperative undertaking through various conferences of many parties concerned in this development."

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Salk Vaccine

A series of bills on the subject of federal controls for supplying Salk vaccine for poliomyelitis have been introduced in Congress. In S. J. Res. 68 the Secretary of Health, Education, and Welfare would be responsible for "promulgation of mandatory rules and regulations regulating the distribution and use of all Salk vaccine during the temporary national emergency" and reporting to Congress recommendations for further legislation, including price fixing. This measure was sponsored by Senators Ives (R., N. Y.), Beall (R., Md.), Bush (R., Conn.), Case (R., N. J.), Duff (R., Pa.), Flanders (R., Vt.), Humphrey (D., Minn.), Lehman (D., N. Y.), Murray (D., Mont.), Saltonstall (R., Mass.), Watkins (R., Utah), Payne (R., Maine), and Kuchel (R., Calif.) and referred to the Committee on Labor and Public Welfare. Identical measures were introduced in the House by Congressman Gamble (R., N. Y.), in H. J. Res. 299, and Congressman Radwan (R., N. Y.), in H. J. Res. 300, which measures were referred to the Committee on Banking and Currency.

Congressmen Fogarty (D., R. I.), Boland (D., Miss.), and Smith (R., Wis.), in H. J. Res. 297, 298, and 302, respectively, and Senator Kefauver, in H. J. Res. 70, have introduced identical measures, which would direct the Secretary of the Department of Health, Education, and Welfare to establish priorities in age groups to receive the vaccine and establish prices per unit of vaccine and an allocation of vaccine to the states. The House measures were referred to the Committee on Banking and Currency and the Senate measure to Committee on Labor and Public Welfare.

Congressman Davidson (D., N. Y.), in H. R. 5983, would, (1) give the President stand-by power to (*a*) establish priorities and contract manufacturers, (*b*) allocate supplies, (*c*) establish ceiling prices at manufacturer or distributor level with no control of the cost of administering the vaccine, and (*d*) require records to be kept on dates, price, and patients vaccinated; (2) make the present provisions as to violations of the Defense Production Act applicable to violations of this act; and (3) make the present law regarding hoarding and accumulation applicable to vaccine. This measure was referred to the Committee on Banking and Currency. Congressman Keating (R., N. Y.), in H. J. Res. 301, would authorize the appropriation of the one million dollars for purchase of Salk vaccine for children whose parents were unable to pay for Salk vaccine inoculations. This measure was referred to the Committee on Interstate and Foreign Commerce.

Senator Hill (D., Ala.), in S. 1925, would "authorize and empower the President to provide for prompt, fair, and effective distribution and use of poliomyelitis vaccine for the purpose of preventing abuses and safeguarding the public interest." This would authorize the President to (1) establish classification and priorities for Salk vaccine; (2) require records by manufacturers, distributors, and persons dispensing vaccine; (3) provide for sale at reasonable prices; (4) provide for purchase and free distribution for immunization purposes; and (5) designate or create new agencies to carry out purposes of this legislation. Section 6 of the bill provides that "any person who willfully performs any act prohibited, or willfully fails to perform any act required by any rule, regulation, or order promulgated under the authority of this Act shall, upon conviction, be fined not to exceed $10,000 or imprisoned for not more than one year, or both." This bill was referred to the Committee on Labor and Public Welfare.

The administration's measure authorizing the appropriation of funds for grants-in-aid programs for immunization to poliomyelitis for children whose families were unable to pay was introduced by Senator Smith (R., N. J.), in S. 1984; Senator Hill (D., Ala.), in 1989; Congressman Priest (D., Tenn.), in H. R. 6286; Congressman Wolverton (R., N. J.), in H. R. 6287; and Congressman Burnside (D., W. Va.), in H. R. 6426. This measure would not prevent the state from setting up free vaccination programs for all. An authorization of 28 million dollars, available until Dec. 31, 1956, is provided in the bill. The administration subsequently agreed to raise this amount to 35 million dollars. The allotments to the state would be determined on the basis of the relative population under age 20 and the state's per capita income. The state with the lowest per capita income would receive enough money to pay for vaccine for 41% of its children. The state with the highest per capita income would receive enough for 15%; and the state with average income enough for 20%. The Senate bills were referred to the Committee on Labor and Public Welfare and the House bills to Committee on Interstate and Foreign Commerce.

Senators Hill (D., Ala.), Murray (D., Mont.), Neely (D., W. Va.), Douglas (D., Ill.), Lehman (D., N. Y.), Kennedy (D., Mass.), and McNamara (D., Mich.), in S. 2147, would make Salk vaccine available free to any community on condition that free vaccination would be available to all children whose parents desire free vaccination. The state would be required to provid that professional medical service would be available to administer the vaccine at no cost to all children whose parents di not want to pay the fees to private physicians for the servic An unlimited appropriation would be authorized. This bill w referred to the Committee on Labor and Public Welfare. Co gressman Rodino (D., N. J.), in H. R. 5987, would amend t Defense Production Act to give the President authority to quire manufacturers to fulfill selected orders for Salk vaccine preference to other orders for such vaccine and "to allocate Salk vaccine in such manner, upon such conditions, and to such extent as he shall deem necessary or appropriate to promote the public welfare. All the authority conferred in the Act would terminate June 30th, 1957." This bill is identical with H. R. 5599 (Rains, D., Ala.), 5611 (Celler, D., N. Y.), and 5696 (Addonizio, D., N. J.), previously reported. These bills were referred to the Committee on Banking and Currency.

Congressman Shelley (D., Calif.), in H. R. 6021, proposes to establish an emergency commission to insure the most effective and equitable distribution of Salk vaccine. The commission could recommend price-fixing legislation. This bill is identical with S. 1691, previously reported in THE JOURNAL, June 18, 1955, page 568. Congressman Tumulty (D., N. J.), in H. R. 6056, proposes to reimburse the states for the cost of Salk poliomyelitis vaccine used in a plan approved by HEW providing that 75% of the children eligible have been inoculated under the state plan. This bill was referred to the Committee on Interstate and Foreign Commission. Congressman Patterson (R., Conn.), in H. R. 6120, would direct the Secretary of the Department of Health, Education, and Welfare to establish priorities in age groups to receive the vaccine and prohibits the sale of vaccin "upon terms or conditions in conflict with the applicable pro gram established by the health department of a state." Violatio would be punishable by a fine of not more than $5,000 or im prisonment for not more than two years or both.

After the voluminous and confusing mass of bills listed abo were introduced and the clamor for them quieted down som what, two bills were reported out of committee, one in t House, H. R. 7126, by Congressman Priest (D., Tenn.). Th was a new bill developed after hearings were held on precedi bills. In the Senate S. 2501 was also a new bill following he ings on other Salk vaccine bills. This was introduced by Senat Hill (D., Ala.), Smith (R., N. J.), Murray (D., Mont.), I (R., N. Y.), Neely (D., W. Va.), Purtell (R., Conn.), Doug (D., Ill.), Bender (R., Ohio), Lehman (D., N. Y.), Allott (Colo.), Kennedy (D., Mass.), and McNamara (D., Mich.). House bill from the Committee on Interstate and Foreign C merce would authorize the Department of Health, Educat and Welfare to make allotments to the states to consist of an unmatched grant based upon 25% of the number of vaccinated eligible persons in the state multiplied by the pro of the cost of vaccine and the state's relative per capita inc (2) a 50-50 matching grant to cover the cost of additional p myelitis vaccine, (3) an additional 20% of the above tw administrative expenses. The Senate bill would amend the P Health Law on general grants to states to authorize out grants without matching to the states for the purchase of vaccine for children under 20 and expectant mothers. If gress does not vote enough money to pay for vaccine f eligibles, the surgeon general will prorate whatever is avai taking into account disease incidence in the state as well a per capita income and population. If the state does not p a program for all eligibles, the state would be required to c with priorities established by the surgeon general.

From the Washington Office of the American Medical Association.

MEDICAL NEWS

CALIFORNIA

Society News.—Dr. Alton Ochsner, professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, will discuss "Carcinoma of the Lung" and Dr. Edward H. Rynearson, professor of medicine, Mayo Foundation, Rochester, Minn., "Radioactive Iodine in the Treatment of Hyperthyroidism" at the meeting of the Alameda-Contra Costa Medical Association, given under the auspices of the staff of the Samuel Merritt Hospital, Aug. 25, 8:15 p. m., at Hunter Hall, 1025 Second Ave., Oakland (TEmplebar 6-2622).

UCLA Medical Center.—The final major step in the development of the new medical center of the University of California at Los Angeles took place July 6, with the opening of the 320-bed teaching hospital. Constructed at a cost of 21 million dollars, the new center combines in one physical plant the schools of medicine and nursing, research facilities, a teaching hospital, outpatient departments, and a biomedical library, which joins it to the new Life Science Building. Creation of the U. C. L. A. Medical Center began in 1946 when the California legislature appropriated funds. The school section of the center was opened last fall, when the schools of medicine and nursing moved in from temporary quarters. On June 19 the medical school graduated its first class.

CONNECTICUT

Symposium on Industrial Health.—The following symposium on industrial health will be presented at the main hospital of the United States Rubber Company, Water Street, Naugatuck, at 2 p. m. on Sept. 22 under the auspices of the committee on industrial health, Connecticut State Medical Society. The program will be moderated by Dr. Alphonse Della Pietra, consulting orthopedic surgeon of the company and attending orthopedic surgeon, St. Mary's Hospital, Waterbury.

Low Back Conditions Found on Preemployment Physical Examination as Related to Industrial Liability, David M. Bosworth, New York.
Treatment of Hip Injuries, Frederick R. Thompson, New York.
Secondary Repair in Severe Industrial Hand Injuries, J. William Littler, New York.
Hematic and Neoplastic Health Hazards in the Rubber Industry, Wilhelm C. Hueper, Bethesda, Md.

DISTRICT OF COLUMBIA

Doctors' Orchestra.—The newly organized Doctors' Orchestra of Washington, D. C., is open to doctors, dentists, veterinarians, nurses, and their families. President of the group is Dr. Richard H. Todd; vice-president and concert master, Dr. Isadore M. Alpher. The first rehearsal was held recently under the baton of Howard Mitchell, conductor of the National Symphony Orchestra.

Personal.—Dr. John W. Cronin, chief, division of hospital facilities, U. S. Public Health Service, was given an honorary degree of doctor of science on June 6 by Miami University, Oxford, Ohio.——Georgetown University, Washington, D. C., has received a gift of $100,000 from Mr. Hugh A. Grant, Bradford, Pa., for a 10 year study of organ culture under the direction of Dr. Robert J. Coffey, professor of surgery.——Dr. Irvin Hantman, Washington, D. C., received the first annual award of the alumni of Episcopal Eye, Ear and Throat Hospital for "distinguished work in otology and diseases of the ear."

ILLINOIS

University News.—Dr. Frederick W. Merrifield, chairman, executive committee, Northwestern University Cleft Lip and Palate Institute, announces that Mrs. Eleanor P. Moses, previously executive secretary, has been appointed administrator of the institute.

Clinics for Crippled Children.—The University of Illinois division of services for crippled children has scheduled the following clinics to which any private physician may refer or bring children for examination or consultative services:

Aug. 17, Alton (Rheumatic Fever), Alton Memorial Hospital; Chicago Heights, St. James Hospital.
Aug. 18, Rockford, St. Anthonys Hospital.
Aug. 23, Peoria, Children's Hospital; Effingham (Rheumatic Fever), St. Anthony's Emergency Hospital.
Aug. 24, Springfield (Cerebral Palsy), Memorial Hospital; Elgin, Sherman Hospital.
Aug. 25, Bloomington, A.M. (General), P.M. (Cerebral Palsy), St. Joseph's Hospital.
Aug. 26, Chicago Heights (Rheumatic Fever), St. James Hospital.

Chicago

University News.—The Max and Leola S. Epstein Foundation has presented the Chicago Medical School with a gift of $150,000 for "support of medical education and medical service."——A grant of $2,000 in support of the Chicago Medical School from the Sidney Hillman Foundation was recently presented to Dr. John J. Sheinin, president of the school, by representatives of the Chicago Joint Board of the Amalgamated Clothing Workers of America.

Parts of Medical Center Completed.—The West Side Medical Center, which has been called "an empire of medical skill," occupies 478 acres, extending from Ashland Avenue to Oakley Boulevard and from the Congress Street Expressway south to the railroad tracks at 14th and 15th streets. It includes Cook County Hospital, Presbyterian Hospital and school of nursing, University of Illinois hospital and colleges of medicine, dentistry and pharmacy, Loyola University schools of medicine and dentistry, Chicago Medical School, and many new facilities erected since the district was created by the state legislature in 1941. During the last four years 15 major projects, representing building costs of 45.5 million dollars, have been completed on land made available by the Medical Center Commission. These include the east Dental-Medical-Pharmacy Building, University of Illinois; the William Healy Residential School for Children; the Chicago State Tuberculosis Sanitarium; Cook County Hospital Dormitory for Interns; Veterans Administration Hospital; Cook County Graduate School of Medicine; and numerous offices and residential and administrative projects. Among the earliest buildings to be erected were Cook County Hospital (1875) and Rush Medical College (1876). Presently under construction is the Loyola University Stritch School of Medicine and College of Dentistry Building.

MARYLAND

Society News.—Newly elected officers of the radiological section of the Baltimore City Medical Society include: Dr. Walter L. Kilby, Baltimore, chairman, and Dr. Nathan B. Hyman, Baltimore, secretary-treasurer.

Dr. Rysanek Honored.—At a dinner honoring his 50th anniversary of general practice, Dr. William J. Rysanek Sr., Baltimore, received special greetings from Mayor D'Alesandro, who designated him as "an honored and outstanding citizen of Baltimore" and from Dr. Huntington Williams, Baltimore, commissioner of health, who wrote: "Such a splendid life of unselfish devotion to the many fortunate persons who have come under your care during these many years is an inspiration to all of us and is a cause for rejoicing on the part of the city of Baltimore." Dr. Rysanek's sons, William J. Rysanek Jr. and Emil J. Rysanek, Baltimore, are physicians.

MASSACHUSETTS

New Harvard Surgical Unit.—With the reestablishment of a surgical unit at the Boston City Hospital and the creation of the new Sears Surgical Laboratory, the Harvard Medical School, Boston, will resume participation in surgical research, teaching, and patient care at the hospital, renewing an affiliation that lasted

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

from the founding of the hospital in 1861 until 1942. The renewal of service was made possible largely by the bequest of Charles H. Tyler, Boston, who in 1931 left a public charitable trust as a memorial to the late Dr. George G. Sears, formerly clinical professor of medicine at Harvard and a trustee of the hospital. The fund now amounts to well over $1,500,000. Dr. J. Englebert Dunphy will be Harvard Professor of Surgery and director of the new unit, which was scheduled to open in July, with Dr. Charles C. Lund as surgeon-in-chief.

NEBRASKA

Personal.—Dr. Benjamin B. Wells, professor of medicine, Creighton University School of Medicine, Omaha, recently served as professor of medicine pro tem at Georgetown University School of Medicine, Washington, D. C., in accordance with a custom of having leading teachers from other schools brought in for a short period to broaden the educational opportunities of the students and house staff. During this period the "pro tem" professor carries on the educational activities of Dr. Harold J. Jeghers, director of the department of medicine.

Institute on Neuromuscular and Rheumatic Diseases.—Creighton University School of Medicine, Omaha, together with the Nebraska State League for Nursing and the Nebraska Arthritis and Rheumatism Foundation, will sponsor an Institute on Rehabilitation of Neuromuscular Diseases and Rheumatic Diseases at Creighton Memorial St. Joseph's Hospital Sept. 8-10. Guest speakers will be Dr. Joseph G. Benton, coordinator of education and research at the Institute of Physical Medicine and Rehabilitation in New York, Dr. William A. Spencer, associate professor of pediatrics, Baylor University College of Medicine, Houston, Texas, and Dr. William D. Robinson, professor of internal medicine, University of Michigan Medical School, Ann Arbor. For information write Dr. Harold N. Neu, Medical Director, Department of Rehabilitation, Creighton Memorial St. Joseph's Hospital, Omaha.

NEW HAMPSHIRE

Workshop on Epilepsy.—A workshop on epilepsy will be held Sept. 14, 10 a. m.-4 p. m., at the New Hampshire Highway Hotel, Concord, under the sponsorship of the state department of health, Crippled Children's Services; state department of education; and the New Hampshire Pediatric Society. Registration may be made through State Department of Health, Crippled Children's Services, 17 Capitol St., Concord.

NEW JERSEY

Medical Director of A. T. and T.—Dr. L. Holland Whitney, Morristown, medical director for New Jersey Bell Telephone Company since 1948, has been appointed medical director for the American Telephone and Telegraph Company. Dr. Whitney was medical director for the Sperry Gyroscope Company in Long Island, N. Y., during World War II. He has been secretary of the Academy of Medicine of New Jersey, a vice-president of the New Jersey Industrial Medical Association, a fellow of the Academy of Medicine of the northern New Jersey section of occupational health, and chairman of the committee on alcoholism for the Essex County Service for the Chronically Ill.

NEW YORK

University News.—The office of administration, State University of New York College of Medicine at New York City, Brooklyn, has moved from 350 Henry St., Brooklyn 1, to 496 Clarkson Ave., Brooklyn 3.

Israel Strauss Lecture.—The first Israel Strauss Lecture, "The Application of the Experimental Method of Psychiatric Therapy," was delivered at Hillside Hospital, Glen Oaks, April 10 by Dr. David McK. Rioch, director of the neuropsychiatric division of the Army Medical Service Graduate School at the Walter Reed Army Hospital, Washington, D. C. These lectures, originally conceived while Dr. Strauss was alive, will now be given as annual memorial lectures. Dr. Morris B. Bender, New York City, is chairman of the lecture committee.

Ciba Award to Dr. Gross.—The 1955 Ciba award for meritorious accomplishments in the field of endocrinology was presented to Dr. Jack Gross, associate professor of anatomy, State University of New York College of Medicine at New York City in Brooklyn, at the annual meeting of the Endocrine Society in Atlantic City, N. J. He was cited for his work on the thyroid gland, since the introduction of radioiodine in the early 1940's, and especially for his isolation of a new iodine compound, triiodothyronine, in human blood. Together with Dr. R. Pitt-Rivers at the National Institute for Medical Research, London, England, Dr. Gross isolated triiodothyronine from the thyroid of cattle, explored its physiological properties, and synthesized it chemically. In addition to a stipend of $1,800, the Ciba award provides $700 for expenses if the recipient wishes to pursue, within two years, special investigative work at a laboratory other than his own. Dr. Gross will take a six month leave from the state university next February, when he hopes to work in the laboratory of Dr. Hans Krebs, Nobel Laureate, at Oxford, England, in studies pertaining to enzymatic reactions involving triiodothyronine.

New York City

Rado Lectureship.—In honor of Dr. Sandor Rado, who has retired from his position as director of the Columbia Psychoanalytic Clinic for Training and Research, a lectureship has been established in the department of psychiatry, Columbia University College of Physicians and Surgeons. On July 1, Dr. Abraham Kardiner succeeded Dr. Rado as director of the clinic.

First Graham Award to Dr. Whipple.—Dr. Allen O. Whipple, professor emeritus of surgery, Columbia University College of Physicians and Surgeons, received the first Graham award for outstanding contributions to surgery at a ceremony, June 6, at Washington University, St. Louis. Funds for the award were set up by associates and former students of Dr. Evarts A. Graham, emeritus Bixby Professor of Surgery at Washington University School of Medicine, St. Louis, at the time of his retirement in 1951. The medal will be awarded every three or four years to the surgeon who, in the opinion of the selection committee, has made the most significant contributions to his profession. Dr. Whipple is director of a new project in which the American College of Surgeons will be associated with the U. S. Foreign Operations Administration in bringing to this country doctors from the NATO countries for training in American hospitals.

Personal.—Dr. Irving B. Goldman has been appointed as attending otolaryngologist for rhinoplasty to the Mount Sinai Hospital. ——Dr. Lewis Robert Wolberg, associate clinical professor of psychology at the New York Medical College, Flower and Fifth Avenue Hospitals, discussed "Modern Trends in Hypnotherapy" before the hospital staff of the Veterans Administration Hospital at Northport, L. I., June 3.——Dr. Oskar Diethelm, professor of psychiatry, Cornell University Medical College, addressed the hospital staff of the Veterans Administration Hospital at Northport, L. I., June 7 and 8, his topics being "Research Methodology and Mental Illness" and "Psychodynamics of Schizophrenia."——Dr. Samuel Weiss, editor-in-chief of the *American Journal of Gastroenterology* since its inception in 1934, was honored on his 70th birthday by the New York Academy of Gastroenterology, which presented him with an illuminated plaque containing a set of resolutions recognizing his 70th birthday and his accomplishments in medicine.——Dr. Joseph Hirsh has been appointed associate professor of preventive and environmental medicine at the new Albert Einstein College of Medicine.——Dr. Howard A. Rusk, chairman, and Eugene J. Taylor, B.S., assistant professor, department of physical medicine and rehabilitation, New York University College of Medicine, have been awarded the Order of Merit José Fernandez Madrid by the government of Colombia. Dr. Rusk and Mr. Taylor, with Capt. Thomas J. Canty, U. S. Navy Hospital, Oakland, Calif., recently conducted clinics, lectures, and demonstrations in Colombia, where they acted as consultants for the new 850-bed military hospital being erected in Bogota.

UTAH

Personal.—Dr. George A. Spendlove, Salt Lake City, director of the Utah State Department of Health since Oct. 3, 1950, recently notified the board of health of his intention to resign.

State Medical Meeting.—The Utah State Medical Association will hold its annual meeting at the Hotel Utah, Salt Lake City, Sept. 8-10. The address of welcome will be delivered by Dr. Charles Ruggeri Jr., Salt Lake City, president, at 8:45 a. m. Thursday. Dr. Elmer Hess, Erie, Pa., President, American Medical Association, will speak at the banquet Friday, 7:30 p. m., on "Medicine—Person to Person." On Saturday at 9:30 a. m. Dr. Hess will present "Treatment of Kidney and Bladder Infections." Dr. Rutherford T. Johnstone, Los Angeles, a member of the Council on Industrial Health of the A. M. A., will discuss "Industrial Medicine" on Thursday at 11:30 a. m. and "Occupational Diseases: Their Diagnostic Approach" Saturday noon. "Malpractice Litigation and Prevention Programs" is the subject that will be considered by Mr. Edwin J. Holman, Chicago, member of the Law Department of the A. M. A. and Executive Secretary of the Judicial Council, Thursday, 3:15 p. m. Other out-of-state speakers and their first presentations include:

Frank Glenn, New York, Surgical Treatment of Biliary Tract Disease.
James S. Shipman, Philadelphia, Some Recent Advances in Cataract Surgery.
Gordon Meiklejohn, Denver, Viral Diseases.
Verne T. Inman, San Francisco, Mechanisms of Deep Somatic Pain—Anatomical and Physiological Observations.
Carlton N. Price, Washington, D. C., Office Gynecology.
Horace E. Campbell, Denver, Automobile Crash Injuries.
H. Russell Fisher, Los Angeles, Role of the Pathologist in Diagnosis and Management of Cancer of the Breast.
Charles L. Eckert, St. Louis, New Approaches in Management of Cancer of the Breast.
Richard H. Chamberlain, Philadelphia, Radiotherapeutic Approaches to Cancer of the Breast.
Danely P. Slaughter, Chicago, Surgical Treatment of Cancer of the Lip and Mouth.
Carlton N. Price, Washington, D. C., Indications for Removal of Female Pelvic Organs.

Dr. Ruggeri will serve as moderator for a round-table luncheon Thursday noon, and Dr. Slaughter will moderate the round-table discussion Friday, 11 a. m. At 12 noon Friday, there will be a round-table luncheon during which there will be a talk on recent advances in cancer research. The Friday session will close with a round-table discussion moderated by Dr. Eckert. The woman's auxiliary will meet simultaneously.

WEST VIRGINIA

Hospital News.—The West Virginia Board of Health recently approved the release of federal funds available under the Hill-Burton Act for four hospital projects in the state: Charleston General Hospital, four-story nurses' home, $418,566; Ohio Valley General Hospital, Wheeling, additional portion of funds heretofore appropriated for a chronic ward and mental wards, $339,820; Wheeling-Ohio County Health Center appropriation toward a new two million dollar building, $125,900; and Elizabeth Coplin Leonard Memorial Hospital, Buckhannon, 10-bed addition and new operating room and laboratory, $230,100.

Health Education Workshop.—The 4th Annual Health Education Workshop and the 31st Annual State Health Conference of the West Virginia Public Health Association will be held at the Daniel Boone Hotel, Charleston, Sept. 7-9. The theme for the workshop will be "Current Developments in Health Education in West Virginia" and the conference theme, "What Is Happening in Public Health in West Virginia?" Executive directors of state voluntary health agencies will appear on the program being prepared for the workshop. Subjects to be discussed include "Current Status of Public Health in West Virginia" and "Local Responsibility for Providing Local Health Services." One of the main topics for discussion at the State Health Conference will be "Current Problems in Maternal and Child Health." Speakers will include Miss Ruth Taylor, chief, nursing section, Children's Bureau, and Dr. Samuel M. Wishik, professor of maternal and child health, graduate school of public health, University of Pittsburgh.

GENERAL

Heart Association Research Grants.—The American Heart Association and its affiliates have jointly awarded grants-in-aid totaling $723,972.45 to 149 scientists engaged in research in the field of heart and blood vessel diseases. The new grants, which are additional to 110 fellowship awards announced earlier this year, bring the total allocated by the association to underwrite scientific research during the year that began July 1 to $1,418,972. The association and its affiliates have allocated almost 11 million dollars for research support since the association became a voluntary health agency in 1948.

Abstracts for Meeting of Psychosomatic Society.—The American Psychosomatic Society, which will hold its 13th annual meeting at the Sheraton Plaza Hotel, Boston, March 24-25, 1956, requests that titles and abstracts of papers for consideration for the program be received no later than Dec. 1. Abstracts should be submitted in sextuplicate, for the program committee's consideration, to the chairman, Dr. Stanley Cobb, 551 Madison Ave., New York 22. Other members of the committee are Drs. Carl Binger, Cambridge, Mass.; Daniel H. Funkenstein, Boston; Theodore Lidz, New Haven, Conn.; I. Arthur Mirsky, Pittsburgh; and Harold G. Wolff, New York.

"Sight-Saving Month."—Plans for the fifth annual September "Sight-Saving Month" campaign to mobilize efforts against the increasing threat of blindness in this country have been announced by Dr. Franklin M. Foote, executive director of the National Society for the Prevention of Blindness (1790 Broadway, New York 19). According to Dr. Foote, blindness in the U. S. has reached the rate of more than 27,000 new cases annually. During the 1955 September campaign, the nation's radio, television, newspapers, magazines, and transit advertising companies will contribute time and space to various forms of sight-saving messages. Publications on eye care for children and adults are available from the National Society for the Prevention of Blindness.

Awards and Fellowships in Endocrinology.—The Endocrine Society announces that nominations for the medal of the Endocrine Society, the Ciba award, and the Ayerst, McKenna and Harrison Fellowship may be submitted by any member of the society on forms obtainable from the Office of the Secretary, 1200 N. Walker St., Oklahoma City 3, which should be returned, completed, to the secretary, not later than Nov. 1. The Ciba award, to recognize meritorious accomplishments in the field of clinical or preclinical endocrinology by an investigator not more than 35 years of age, is now $1,800. If within 24 months the recipient should choose to use the award toward further study in a laboratory other than that in which he is at present working, it will be increased to $2,500. The Ayerst, McKenna and Harrison Fellowship, established in 1947, is designed to assist men or women of exceptional promise in furthering their advancement toward a career in endocrinology. The fellowship is awarded in alternate years; e. g., 1955, 1957. The stipend, which will not exceed $5,000, may be divided into two fellowships in varying amounts in accordance with the qualifications of the appointees. Individuals with the M.D. or Ph.D. degree, or candidates for either of these degrees, are eligible for appointment. Proposals for appointments as scholars of the Endocrine Society should be made in writing by the applicant and sent to the secretary of the society by Nov. 1. Notice of awards to successful nominees and applicants will be made not later than Dec. 1.

Surgeons Meeting in Philadelphia.—The United States and Canadian sections of the International College of Surgeons will hold their 20th annual congress at the Convention Hall in Philadelphia Sept. 12-15. Dr. Arnold S. Jackson, Madison, Wis., is president of the U. S. section, and Dr. Lyon H. Appleby, Vancouver, B. C., is president of the Canadian section. Dr. Moses Behrend, Philadelphia, serves as general chairman of the congress and Dr. Harry E. Bacon, Philadelphia, as chairman of the program committee. Among the speakers at the opening assembly will be Joseph S. Clark Jr., mayor of Philadelphia; Dr. W. Edward Chamberlain, president of the Philadelphia County Medical Society; and Dr. Temple S. Fay, professor and head of the department of neurosurgery, Woman's Medical

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Tex., Sept. 17. Dr. E. C. Bebb, Broad St., Wichita Falls, Tex., Chairman.

Oregon State Medical Society, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Catter, 1020 S.W. Taylor St., Portland 5, Secretary.

Pacific Dermatologic Association, Mexico, D. F., Mexico, Aug. 22-24. Dr. Ben A. Newman, 436 N. Roxbury Drive, Beverly Hills, Calif., Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Postgraduate Assembly in Endocrinology and Metabolism, Indianapolis, Sept. 26-Oct. 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

Regional Meetings, American College of Physicians:

Jamestown, N. D., Sept. 10. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

Reno Surgical Society, Reno, Nev., Aug. 18-20. Dr. James R. Herz, 509 Humboldt St., Reno, Nev., Secretary.

Rocky Mountain Radiological Society, Shirley-Savoy Hotel, Denver, Aug. 18-20. Dr. John H. Freed, 4200 East 9th St., Denver 20, Secretary.

Society of General Physiologists, Marine Biological Laboratory, Woods Hole, Mass., Sept. 9-10. Dr. A. M. Shanes, National Institutes of Health, Bethesda 14, Md.

Southwestern Surgical Congress, Muehlebach Hotel, Kansas City, Mo., Sept. 5-7. Dr. C. M. O'Leary, 207 Plaza Court Bldg., Oklahoma City, Secretary.

Tennessee Valley Medical Assembly, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

U. S. Chapter, International College of Surgeons, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Union Bldg., Salt Lake City, Sept. 8-10. Mr. H. Bowman, 42 S. Fifth East St., Salt Lake City 2, Executive Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. Dr. James P. Hammond, 337 South St., Bennington, Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

Western Association of Railway Surgeons, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

West Virginia State Medical Association, White Sulphur Springs, Aug. 18-20. Mr. Charles Lively, P. O. Box 1031, Charleston 24, Executive Secretary.

CALIFORNIA: *Written.* Los Angeles, Aug. 22-25; and Sacramento, Oct. 17-20. *Oral and Clinical Examinations for Foreign Medical School Graduates.* Los Angeles, Aug. 21; and San Francisco, Nov. 13. *Oral Examination for Reciprocity Applications.* Los Angeles, Aug. 20; and San Francisco, Nov. 12. Sec., Dr. Louis E. Jones, Room 536, 1020 N St., Sacramento.

MONTANA: *Examination and Reciprocity.* Helena, Oct. 4-5. Sec., Dr. Sidney A. Cooney, 7 West 6th Ave., Helena.

NEW HAMPSHIRE: *Examination and Reciprocity.* Concord, Sept. 14. Sec., Dr. John S. Wheeler, 107 State House, Concord.

NEW MEXICO:* *Examination and Reciprocity.* Santa Fe, Nov. 21-22. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

OHIO: *Endorsement.* Columbus, Aug. 29-30 and Oct. 3-4. Sec., Dr. H. M. Platter, Wyandotte Bldg., Columbus 15.

ALASKA:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: *Examination.* Denver, Sept. 14-15. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

MICHIGAN: *Examination and Endorsement.* Detroit and Ann Arbor, Oct. 14-15. Sec., Mrs. Anne Baker, 410 W. Michigan Ave., Lansing 15.

OKLAHOMA: *Examination.* Oklahoma City, August 26-27. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination.* Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

TEXAS: *Examination.* Various cities to be determined by number of applicants from the various areas, October. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

WISCONSIN: *Examination.* Madison, Sept. 23; Milwaukee, Dec. 3. Sec., Mr. William H. Barger, 621 Ransom St., Ripon.

ALASKA: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, August 15

NBC-TV, 9 p. m. EDT. "Medic" continues its summer reruns with a repeat of last season's "Dr. Impossible."

MAGAZINES

Ladies' Home Journal, August, 1955

"Fountain of Fellowship for Former Mental Patients," by Margaret Hickey

Fountain House in New York City is a "social center for former mental patients trudging a hard road back to recovery. . . . Over 1000 former patients have belonged to the club in the past seven years and less than 4 per cent of them ever had to return to a mental ward."

Sports Illustrated, August 1, 1955

"Austria's Fountain of Youth," by Paul Deutschman

"The European institution of the spa or watering-place where well-heeled people come a month or so each year to be sprayed, irrigated, vaporized and generally made over by natural waters, has no real counterpart in America today." The author reports on Bad Gastein, 60 miles from Salzburg, where the specialty is "revitalization of abused or disused tissue. . . . There are five specific Gastein cures: the thermal baths and drinking cure for overall revitalization; the vapor baths for localized treatments; the underwater therapy for aftereffects of paralysis; and the amazing thermal gallery for intense treatments."

Town Journal, August, 1955

"How Some Towns Get Doctors," by Clyde Hostetter

A report on the success of the "Kansas Plan" for getting doctors to practice in rural communities. In conclusion, the article says: "If you think [similar action] is needed in your town and state, write for information to: Council on Medical Service, American Medical Association . . . or get in touch with your state medical association."

Good Housekeeping, September, 1955

"The Family Medicine Chest," by Maxine Davis

Good Housekeeping's medical reporter outlines eight suggestions for keeping a proper medicine chest. Points included range from a list of "must" supplies to warnings against keeping medicines too long and against giving drugs to others who seem to have the same condition for which the medication was prescribed.

Pageant, September, 1955

"Are You Capable of Suicide?" by Irwin Ross

"You can help to prevent suicide by being aware of its causes and of the tell-tale signs which usually indicate the suicide-prone. . . . If you think someone you know is greatly depressed, is brooding excessively, is unnaturally concerned with morbid thoughts and death, if you think he is possibly suicidal, get professional help for him quickly."

"TB: The Return of a Killer," by Henry Lee

"The false belief that TB is 'nothing to worry about anymore' threatens the health of all of us." The author quotes Dr. Richard R. Trail, rehabilitation chairman of the International Union Against Tuberculosis, as saying: "When death occurs, a tuberculosis case ceases to be a danger to the public health. But the public does not yet realize that every decline in the death rate means a certain added increase to the infectious rate."

Parade, July 31, 1955

"The Patients Who Drive Us Crazy," by Dr. Keith Hammond

An Indiana physician "sticks his neck out (in a friendly way) to list 10 irritating 'office types.'" Dr. Hammond says he made up the catagories "not in malice, or to point the finger at specific individuals, but in the belief that enlightenment breeds good will."

The American Legion Magazine, August, 1955

"Is Dieting Being Overdone?" by Tom Mahoney

Dieting "has been aptly termed 'the great American obsession.'" The author points out that if one is truly obese or definitely underweight, he should seek help but warns against dieting if it is unnecessary. In one section he quotes Dr. James R. Wilson, former Secretary of the American Medical Association's Council on Foods and Nutrition, as saying: "Special diets must be tailored to fit the specific needs of individual people. Therefore, diagnosis is essential before a proper diet can be formulated. This can be done only by a physician."

DEATHS

Schiller, Alfred Albert, Chicago; born in Chicago Jan. 17, 1916; University of Illinois College of Medicine, Chicago, 1942; served an internship in the navy and later engaged in aviation medicine research at the Naval Medical Research Institute at Bethesda, Md.; member of the American Physiological Society, the Society of Experimental Biology and Medicine, the Histamine Club, and the American Association of University Professors; fellow of the Institute of Medicine of Chicago and of the American Association for the Advancement of Science; member of Alpha Omega Alpha and secretary of the Chicago Professional Colleges chapter of Sigma Xi; assistant professor of physiology at his alma mater in 1947 and was named associate professor in 1951; author of many scientific articles; died in Palo Alto, Calif., April 21, aged 39, of pulmonary embolism.

Klepper, Julius Idel ⊕ New York City; born in Romania April 11, 1881; Long Island College Hospital, Brooklyn, 1909; also a pharmaceutical chemist; professor of otolaryngology at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons and the New York Academy of Medicine; served on the staff of the Manhattan Eye, Ear and Throat Hospital; associate attending otolaryngologist at New York Polyclinic Medical School and Hospital; a draft board examiner during World Wars I and II; in 1929 the Romanian government bestowed on him the Order of Commander of the Crown for his services to Romania; work on behalf of France in this country won him the award of the Palmes Academiques; died June 15, aged 74, of coronary disease.

Neumarker, William Richard Carl ⊕ Columbus, Neb.; born in Luxemburg, Germany, May 18, 1878; Central Medical College of St. Joseph, Mo., 1900; later studied abroad; past vice-president of the Nebraska State Medical Society and the Platte County Medical Society; at one time county physician; served overseas during World War I; one of the two Nebraska delegates at the organization of the American Legion in Paris in 1918; at one time practiced in Edgemont, S. D., where he was a member of the city council and mayor; active in various medical groups in the state, serving on the board of the Crippled Children's Clinic and the board of the Child Saving Institute; surgeon of the Union Pacific Railroad for many years; on the staff of St. Mary Hospital, where he died May 8, aged 76, of ruptured aortic aneurysm.

Seibels, Robert Emmet ⊕ Columbia, S. C.; born in Columbia in 1890; Columbia University College of Physicians and Surgeons, New York City, 1914; specialist certified by the American Board of Obstetrics and Gynecology; charter member and past-president of the South Atlantic Association of Obstetricians and Gynecologists; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served during World War I; director of the Bob Seibels Jr. Memorial Laboratory; consultant at Columbia Hospital, the South Carolina State Hospital, and Camden (S. C.) Hospital; died in May, aged 64.

Stewart, Howard Coke ⊕ Albany, N. Y.; University of Nebraska College of Medicine, Omaha, 1920; specialist certified by the American Board of Public Health; member of the American Trudeau Society; at one time on the faculty of Vanderbilt University School of Medicine in Nashville, Tenn., and the Johns Hopkins University School of Hygiene and Public Health in Baltimore; member of the tuberculosis division of the state board of health; formerly state epidemiologist for the Tennessee State Health Department; died in Memorial Hospital May 27, aged 57, of cerebral hemorrhage and hypertension.

Allen, Horatio Cushing ⊕ New Bedford, Mass.; Harvard Medical School, Boston, 1901; fellow of the American College of Surgeons; on the staff of St. Luke's Hospital, where he was president of the surgical staff from 1923 to 1931, and where he died June 29, aged 80, of acute peritonitis.

Allen, William Lawson, Rising Star, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1915; died June 9, aged 70, of a heart attack.

Beattie, Barbara ⊕ Littleton, N. H.; Cornell University Medical College, New York City, 1924; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics and the New England Pediatric Society; member of the state board of health; on the staff of the Littleton Hospital; died May 23, aged 57.

Birmingham, Eugene Emmett ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; specialist certified by the American Board of Otolaryngology; for many years on the staff of the Illinois Eye and Ear Infirmary; attending surgeon on the staff of Grant Hospital, where he died July 3, aged 75, of cancer.

Bitzer, Emory West ⊕ Hernando, Fla.; University of Virginia Department of Medicine, Charlottesville, 1903; fellow of the American College of Physicians; member of the Association for the Study of Internal Secretions; past-president of the Hillsborough County Medical Society; died in Tampa June 7, aged 72, of cerebral hemorrhage.

Carter, James Daniel, Silver Spring, Md.; Cornell University Medical College, New York City, 1940; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; certified by the National Board of Medical Examiners; served during World War II and was awarded the Navy Cross, Purple Heart, and the Presidential Unit citation; died in Baltimore April 23, aged 38, of subacute glomerulonephritis.

Carter, Norwood William, Holden, La.; Memphis (Tenn.) Hospital Medical College, 1910; died in Baton Rouge May 29, aged 73, of congestive heart failure.

Deardorff, Frank Benson ⊕ Berwyn, Ill.; University of Illinois College of Medicine, Chicago, 1935; founding fellow of the American Academy of Obstetrics and Gynecology; past-president of the medical staff and chief of obstetrics of MacNeal Memorial Hospital, where he died July 12, aged 49, of Banti's disease.

Dixon, Rufus Herbert ⊕ Rockville Centre, N. Y.; Jefferson Medical College of Philadelphia, 1918; on the staff of the South Nassau Communities Hospital; died in Municipal Hospital, Tampa, Fla., June 30, aged 72, of coronary heart disease.

Donovan, William Francis, Bay Head, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York City, 1890; served on the staff of the Monmouth Memorial Hospital in Long Beach; died June 15, aged 85.

Dow, Joseph Abner ⊕ West Topsham, Vt.; University of Vermont College of Medicine, Burlington, 1899; for many years health officer; on the staff of the Barre City (Vt.) Hospital; died in the Mary Hitchcock Hospital in Hanover, N. H., June 10, aged 81.

Duiker, Henry, Traverse City, Mich.; Rush Medical College, Chicago, 1920; member of the Michigan State Medical Society; fellow of the American College of Chest Physicians; on the staff of the Traverse City State Hospital; died June 24, aged 61, of myocardial infarction.

Holtzendorff, Charles F. ⊕ St. Petersburg, Fla.; Medical College of Indiana, Indianapolis, 1895; at one time practiced in Plymouth, Ind., where he was mayor; died April 27, aged 85, of ruptured abdominal aortic aneurysm.

Huckabay, Durward Allison ⊕ Seattle; Tulane University of Louisiana School of Medicine, New Orleans, 1925; member of the American Academy of General Practice; served during World War I; on the staffs of the Maynard Hospital and Columbus Hospital, where he died June 15, aged 53, of coronary thrombosis.

⊕ Indicates Member of the American Medical Association.

Jones, Joseph Francis, Clinton, Ala.; Atlanta (Ga.) College of Physicians and Surgeons, 1902; died March 5, aged 80, of a cerebral accident.

Jones, Robert Young ⊕ Hutchinson, Kan.; Rush Medical College, Chicago, 1907; fellow of the American College of Surgeons; on the staffs of the St. Elizabeth Mercy Hospital and Grace Hospital, where he died July 3, aged 73, of cerebral thrombosis.

Kahan, Harry Leo ⊕ Gary, Ind.; Indiana University School of Medicine, Indianapolis, 1919; served during World War II; on the staff of the Methodist Hospital until his retirement; died in Tucson, Ariz., July 1, aged 60, of coronary disease.

Katherman, Charles Augustus ⊕ Sioux City, Iowa; Rush Medical College, Chicago, 1906; served in France during World War I; died June 10, aged 77, of cerebral thrombosis.

Kelly, John Edward ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1927; member of the Industrial Medical Association; on the staff of the Syracuse General Hospital, where he died July 3, aged 55, of myocardial infarction.

Kirkendall, Henry Laing ⊕ Worcester, Mass.; Long Island College of Medicine, Brooklyn, 1931; specialist certified by the American Board of Obstetrics and Gynecology; member of the New England Obstetrical and Gynecological Society; served during World War II; on the staffs of the Milford (Mass.) Hospital, Webster (Mass.) District Hospital, Fairlawn, Memorial, and St. Vincent hospitals; died May 8, aged 49, of coronary artery disease.

Knoff, Frederick Henry ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1905; an associate member of the American Medical Association; for many years on the faculty of his alma mater, and on the staff of the University Hospital; died in Cazenovia May 26, aged 77, of arteriosclerosis.

Kreutzer, Frederick Laurence, Vallejo, Calif.; University of California Medical School, San Francisco, 1944; specialist certified by the American Board of Surgery; served in the Medical Corps of the U. S. Naval Reserve; on the staff of the Kaiser Foundation Hospital; died June 19, aged 35, of injuries received in an automobile accident.

Leonard, Eileen Mary ⊕ San Francisco; Stanford University School of Medicine, San Francisco, 1922; member of the American Academy of General Practice; died May 29, aged 58, of cancer.

Lukens, Robert William ⊕ Wheeling, W. Va.; University of Pennsylvania School of Medicine, Philadelphia, 1925; fellow of the American College of Surgeons; interned at the Lankenau Hospital in Philadelphia; in 1950 president of the Ohio County Medical Society; served during World War II; on the staffs of the Wheeling Hospital and the Ohio Valley Hospital, where he died July 1, aged 54, of coronary thrombosis with infarction.

McMillin, Virgil Homer, Portland, Texas; Illinois Medical College, Chicago, 1907; died June 23, aged 84, of coronary thrombosis.

Marchand, Austin Flint ⊕ Haubstadt, Ind.; Indiana University School of Medicine, Indianapolis, 1924; president of the Gibson County Medical Society; served during World War I; died in the Welborn Memorial Baptist Hospital, Evansville, May 11, aged 59, of chronic hepatitis.

Neal, Charles Bodine ⊕ Millville, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; also a graduate in pharmacy; an associate member of the American Medical Association; died June 11, aged 88, of lymphosarcoma.

Presnell, J. Will, Scranton, Iowa; State University of Iowa College of Medicine, Iowa City, 1892; died May 11, aged 84.

Randel, Brown Wendel ⊕ El Paso, Texas; Chicago College of Medicine and Surgery, 1914; served during World War II; on the staffs of Hotel Dieu, Sisters' Hospital, and Southwestern General Hospital; died in Ruidosa, N. M., March 22, aged 62, of coronary thrombosis.

Read, Fred Karl ⊕ Akron, Ohio; Western Reserve University School of Medicine, Cleveland, 1916; member of the American Academy of General Practice; served during World War I; received a citation from President Roosevelt and a medal from Congress for his work as an examiner for Selective Service Boards during World War II; on the staffs of the Peoples and Children's hospitals; died in Mount Sinai Hospital in Cleveland June 22, aged 65, of an accidental fall from a roof.

Reiley, William Edgar ⊕ Clearfield, Pa.; Southern Homeopathic Medical College, Baltimore, 1907; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America, and the American College of Radiology; on the staff of the Clearfield Hospital, where he died June 5, aged 72, of chronic congestive heart disease.

Rokala, Henry Emil ⊕ Virginia, Minn.; University of Minnesota Medical School, Minneapolis, 1937; interned at St. Luke's Hospital in Duluth; on the staff of the Virginia Municipal Hospital, where he died June 17, aged 52, of Hodgkin's disease.

Russell, W. A., Oak Ridge, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1891; died in Vicksburg, Miss., May 23, aged 88.

Scheetz, George Conrad ⊕ West Jefferson, Ohio; Starling-Ohio Medical College, Columbus, 1913; member of the American Academy of General Practice; died June 16, aged 78, of myocardial degeneration and arteriosclerosis.

Seelye, Ralph Holland ⊕ Hingham, Mass.; Harvard Medical School, Boston, 1890; fellow of the American College of Surgeons; member of the New England Surgical Society; formerly practiced in Springfield, where he was a trustee of the City Library Association, on the staff of the Springfield Hospital, and during World War II an examining physician at the Army Induction Center; died May 18, aged 90.

Small, Fitz Elmer ⊕ Biddeford, Maine; Medical School of Maine, Portland, 1899; died in the Deaconess Hospital, Boston, April 18, aged 78, of coronary disease.

South, F. Floyd ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1924; clinical instructor in general surgery at his alma mater; served during World Wars I and II; formerly member of the state board of health; county coroner; died June 4, aged 63, of coronary occlusion.

Theobald, John Joseph ⊕ Oak Park, Ill.; Rush Medical College, Chicago, 1920; specialist certified by the American Board of Otolaryngology; assistant professor of laryngology at the University of Illinois College of Medicine in Chicago; member of the American Academy of Ophthalmology and Oto-Laryngology; associated with the West Suburban Hospital, where he died July 5, aged 66, of pancreatitis.

Thornburg, William Vestal ⊕ Guthrie Center, Iowa; State University of Iowa College of Medicine, Iowa City, 1905; member of the American Academy of General Practice; died June 18, aged 75, of cerebral hemorrhage.

Tidd, Arthur C. Harmon, Youngstown, Ohio; Western Reserve University Medical Department, Cleveland, 1909; on the staff of St. Elizabeth Hospital, where he died June 24, aged 74, of intestinal obstruction and bleeding gastric ulcer.

Webster, John B. ⊕ New Bedford, Mass.; College of Physicians and Surgeons, Baltimore, 1914; fellow of the American College of Surgeons; served during World War I; received the Silver Star, and the Verdun medal was given to him by the French government; associated with Acushnet Hospital and St. Luke's Hospital, where he died July 1, aged 68, of coronary occlusion.

Wise, Samuel Howard ⊕ Portland, Ore.; Temple University School of Medicine, Philadelphia, 1920; died June 17, aged 62, of carcinoma of the lung.

CORRECTION

Armentrout, Charles Henry.—In the obituary of the late Dr. Charles Henry Armentrout (THE JOURNAL, July 23, page 1042), it was stated that Dr. Armentrout was a specialist certified by the American Board of Surgery, whereas he was certified by the American Board of Internal Medicine.

FOREIGN LETTERS

AUSTRALIA

Health Service in Australia.—The provision of a comprehensive national health service in Australia is made difficult by the division of the responsibility for health service between the states and the commonwealth (*Australasian Journal of Pharmacy*, April 30, 1955). Health is essentially a constitutional prerogative of the states, therefore all the basic facilities for health such as provision of hospitals, local health control, and sanitary control are state functions. The commonwealth government has, however, devised a comprehensive national health program that is working very successfully. The scheme aims to build up the morale and independence of the Australian people and ensure a vigorous and healthy population.

Governmental assistance in a planned program demands that any permanent scheme must contain certain elements to ensure an effective and economical service for the nation as a whole. Briefly these elements are: 1. The actual costs must be within the financial capacity of the individual and of the nation. 2. The government must have some control over these costs. 3. The plan must have the inherent means for automatic checks and control of costs. 4. Existing facilities, agencies, and proved methods should be used to the greatest practicable extent. 5. The plan must be on a permanent basis and must be organized to permit future development and extension of its machinery to handle any new problems that may arise. 6. The willing cooperation of physicians, pharmacists, hospital managements, and voluntary organizations should be secured by leaving to them as much of the administration and control of the scheme as possible to improve efficiency and minimize operating costs. 7. The individual must be encouraged to retain his sense of personal and social responsibility. 8. The effect of the scheme must be to raise the standard of medical care and treatment available to the community in general and to enable the individual to exercise freedom of choice when selecting the physician, pharmacist, or hospital that is to provide this care and treatment. This scheme aims first at preventing sickness; curtailing the length of sickness if it is not preventable; encouraging research into the causes of the sickness; eradicating sources of infection; and subsidizing hospital and medical insurance to assist individuals so that they may be able to pay their medical and hospital bills. This encourages earlier diagnosis and treatment. All of these assist hospital finances by lessening the number of patients going into hospitals and shortening the period of stay of those needing hospitalization.

Federal Activities.—Federal activities include: 1. The National Health and Medical Research Council, which deals with research. Grants for this purpose have been increased from $140,000 to $420,000 in the last four years. 2. A maternity bonus at the following rates: first child, $42; second and third child, $44.80; fourth and subsequent children $49. If insured at the lowest rates, the mother will also receive $35.28 toward hospital and $21 toward medical care. Child endowment is paid at the rate of 70 cents for the first child and $1.40 for the second and subsequent children to help maintain their nutrition. 3. The constitutions of children are built up by the provision of free milk to school children under 13 years of age throughout Australia, so that their resistance to disease is strengthened. 4. Very sick people are assured of being able to secure the antibiotics and costly drugs that have been discovered recently, by making them free on the prescription of a physician, as are practically all immunizing agents. 5. To ensure the health of the aged, the infirm, and the poor, a free Pensioner Medical Service has been developed to supply free medicines and medical treatment. 6. Tuberculosis has been attacked on a nation-wide scale by encouraging people who suspect themselves of being infected to report through the provision of the most generous tuberculosis allowances in the world, by free roentgenograms, and by the building of tuberculosis hospitals. Extraordinary results have been achieved, as shown by the fact that within the first four years the number of deaths attributable to tuberculosis was cut in half. Also the number of persons receiving allowances, a figure that rose sharply at the commencement of the scheme, is now decreasing as patients are responding to modern treatment and returning to useful occupations and full-time employment in the community. In 1930 tuberculosis accounted for 1,104 of each 10,000 deaths in Australia, but in 1953 the figure was 128. 7. The commonwealth subsidy to a system of voluntary insurance enables the community to meet the unpredictable costs of medical and hospital services.

Federal Government Given No Compulsory Powers.—The constitutional amendment quoted makes it clear that, no compulsory powers on health are given to the federal government. Everything must be done by voluntary cooperation. The commonwealth government has succeeded in establishing a partnership of all agencies dealing with health. The principle of the government's national scheme is to build up a partnership of mutual aid supported and stimulated by government aid. This partnership control permits legal powers to be delegated to professional and insurance organizations to enable them to police, discipline, and control abuse of the scheme. This system of control has proved so effective that the growth of the commonwealth health scheme has been phenomenal. In 1948-1949 total expenditure by the commonwealth and its associated health activities toward relieving sick people of medical and hospital costs was $18,200,000. In 1954-1955, judging from the first six months, the expenditure on these aids to the cost of individual sickness in the community will be $114,044,000, or over six times as much.

The government must be assured of the quality of the drugs for which it is paying large sums of public money and that the drugs provided are capable of achieving the purpose for which they are prescribed. After consultation with the states and the health organizations concerned, therefore, the commonwealth passed the Therapeutic Substance Act to ensure that drugs that are imported, subject to interstate trade, or supplied to the commonwealth or to persons under the National Health Act comply with specified requirements of packaging and labeling and maintain appropriate standards of purity.

Complimentary to this national program, the commonwealth is assisting, by way of money grants, a number of voluntary activities and organizations operating community health services, such as: (1) the Flying Doctor Service, which provides a wonderful service to those who live in isolated areas; (2) the Blood Transfusion Service, which is operated by the Australian Red Cross; (3) the Lady Gowrie Child Centers, which were established for the care of children of preschool age; and (4) the National Fitness Campaign, whereby funds are provided to the various states for the purpose of organization and to six universities to establish lectureships in physical education.

Under an agreement with the University of Sydney, the commonwealth has established a School of Public Health and Tropical Medicine at the University. In 1948 an Industrial Medicine Unit and an Institute of Child Health were established at the school. Fifteen health laboratories are maintained at strategic points throughout the commonwealth. Among other activities are the Commonwealth Serum Laboratories and the Commonwealth X-Ray and Radium Laboratory.

The items in these letters are contributed by regular correspondents in the various foreign countries.

AUSTRIA

Hemorrhage from the Tonsil.—At the meeting of the Society of Physicians of Vienna on April 22, Dr. J. Glaninger reported the case of a patient with a spontaneous oozing hemorrhage from the tonsil. Bleeding ceased after removal of the tonsil, which had been damaged by recurrent peritonsillar abscesses. The histological examination of the gland revealed numerous diapedetic hemorrhages. In all previously reported cases either superficial tonsillar vessels or, more often, vascular erosions were the cause of spontaneous hemorrhage in this region.

Electromyographic Findings in Poliomyelitis.—At the same meeting Dr. K. Pateisky said that the electromyogram reveals the functional organization and its disturbance in normal and in paralyzed muscles. The muscle that has been paralyzed by poliomyelitis shows a reduction in the number of action potentials, by destruction of the anterior horn cells; brief fibrillation potentials as a result of chronically denervated muscle fibers; and hypersynchronism and constant discharge frequency, because of functional weakness of the anterior horn cells. If activation is maintained, there is a decrease in amplitude of the action potentials because of fatigue at the motor end plate. With the aid of anticholinesterases, it is possible to counteract temporarily the electromyographic and clinical signs of fatigue and thus promote the regression of the paresis.

Connective Tissue.—At the same meeting Dr. A. Pischinger of Graz stated that the so-called soft connective tissues (the interstitial and reticular tissues) have important functions in the carbon dioxide, the ion, and the water exchanges and that they are concerned with the functions of enzymes and defense against infection. They contain two primary types of reticular cell, which, in response to certain stimuli, produce free differentiated forms: the macrophages or monocytes and the lymphocytes, with their special forms. The reticular cells of the interstitial cell system are so closely connected with the capillaries and the terminal neuroreticulum that all three must be regarded as a functional unit (interstitial apparatus). By virtue of this organization the interstitial cell system is interwoven into the general regulatory system and is correlated with the nervous and humoral regulatory poles. The close connection with the sympathetic nerves and with the blood exist also in the reticuloendothelial and the lymphatic systems. Here again, the interconnections with the regulatory poles can be demonstrated, but on the basis of simple experiments the reticuloendothelial system and the lymphatic tissues cannot be classed with the interstitial cell system but represent, by virtue of their emission of leukocytes, a third pole of regulation, which could be designated as the "cellular" pole. The functions of the epithelial cells of the parenchyma are influenced by the mesenchyma, that is, by the interstitial apparatus and beyond that by the regulatory poles. This concept of the connective tissue shows that it is a crucial system, which cannot be circumvented in any form of therapy.

Ectopic Teeth.—At the meeting of the Society of Physicians in Vienna on June 10, Dr. H. Baum reported on a woman, aged 40, who had suffered from increasing restriction of nasal breathing on the right side after an attack of influenza. Rhinolaryngological examination revealed what appeared to be a typical rhinolite on the right side of the nasal fossa and evidence of surgical repair of harelip and cleft palate. At operation two bicuspid teeth, the crowns of which projected into the nasal cavity and were covered with incrusted, brownish calcium salts, were removed. There had been a displacement of teeth into the nose with simultaneous rotation and the formation of rhinolites.

Colchicine and Colzemid Therapy in Leukemia.—At the same meeting Dr. Keibl reported on Colzemid (N-methyl-desatetylcolchicine), a derivative of colchicine. It proved highly effective in inducing a remission in patients with chronic granulocytic leukemia. The success of the treatment was shown by a reduction in the number of leukocytes, maturation of cells, diminution in the size of the enlarged spleen, and an improved general condition. While colchicine produces storing of thrombocytes that can be put to use therapeutically without being specific in leukemia, Colzemid, which is fully effective in granulocytic leukemia, does not exert any influence on the thrombopoiesis.

Prevention of Suicide.—At the same meeting Hoff and Ringl stated that, although there are situations in which it is understandable that man is compelled to commit suicide, the question arises of why larger numbers of persons have not committed suicide under extreme stress. The final decision apparently depends on the personality of the subject. Although perhaps in some cases the suicidal attempt differs from actual suicide, a tendency to self-destruction nevertheless is manifested in the attempt, although in an attenuated form, and this has to be taken seriously. In the speakers' series of 882 patients who had been admitted because of a suicidal attempt, a psychic or mental disturbance was the cause of the attempt in all cases. That does not mean that suicide is always a symptom of mental disease. Psychotic and nonpsychotic primary diseases must be differentiated. Involutional psychotic reaction (melancholia) and the dementias, particularly arteriosclerotic dementia, play the most important part among the psychoses. The nonpsychotic primary diseases are hysteria, neurotic reactions, psychopathy, and feeblemindedness. Patients with neurotic personalities who commit suicide are characterized by a typical development of personality that goes back to childhood, and immediately before the suicidal attempt this development of personality induces a "presuicidal syndrome" consisting of repression, inhibited aggression, and flight from reality. The decision to attempt suicide is influenced by an extreme tendency to punish onself, by reverted aggression, and by reports of other suicides. Furthermore, a suicidal attempt often represents an effective appeal to the environment. In recent years many patients with severe poisoning were referred directly to the psychiatric clinic while they were deeply unconscious. Thus the necessity arose to treat intoxications at the psychiatric clinic. The final task of the psychiatric clinic was the care, after discharge, for those whose lives had been saved. Many patients succeeded in adjusting their relationship with their fellow men after the suicidal attempt, and others built up new relationships. Nevertheless, sometime later, about 12% of such patients have a recurrence of their old behavior and again show suicidal tendencies. Thus, after-care is essential. It can be carried out most successfully in cooperation with the department of social welfare. The risk of repeated suicide depends also on the basic psychiatric diagnosis. It is not suggested that every person who has attempted suicide and whose life was saved should be admitted to the psychiatric clinic, but every person whose life was saved should be examined by a psychiatrist. Only in this way can the risk of recurrence, particularly in patients with involutional psychotic reactions, be prevented.

Toxemias of Pregnancy.—At the March 8 meeting of the Austrian Society for Gynecology and Obstetrics, Dr. H. Knaus reported the case of a 20-year-old woman whose first pregnancy had to be interrupted on account of severe hyperemesis. During the second pregnancy she again experienced it. Conservative therapy produced no improvement, but a blood transfusion produced the desired effect. A recurrence of the hyperemesis, several days after the patient was discharged from the hospital, responded again to a blood transfusion.

Dr. R. Schröder of Leipzig said that the most important toxemia of pregnancy is characterized by retention of water, proteinuria, and hypertension. He differentiates three forms of hypertension: true gestosis, hypertension that antedates the pregnancy, and fixed hypertension, with superimposed gestosis. Eclampsia occurs in 0.23% of all births; it is more frequent in urban than in rural regions, and it is seven to eight times more frequent in multiple than in single births. Toxicosis occurs in about 3% of pregnancies, and, in one-third of the patients, it is accompanied by convulsions. Blood replacement is more rapid during pregnancy. In the toxicoses erythrocyte volume is higher than normal, the albumin-globulin ratio is decreased, cystine is reduced, and methionine is increased. Furthermore, the blood sodium level decreases, but sodium becomes concentrated in the tissues favoring the development of edema. About one-third of the patients with gestosis do not show organic changes (functional toxicosis). Organic changes are indicated by the appearance of granular casts, and the renal tubules are damaged as is also the liver. Convulsions are elicited by the sudden onset of vascular spasm. The capacity to bind carbon dioxide is reduced; lactic acid increases in patients with toxicosis from 15 to 60 mg. per 100 cc. The metabolism becomes greatly taxed, but the details of this stress have not been completely explained. The blood iodine content increases from 8 to 24 mg. per 100 cc.; the thyrotropic hormone value reaches 40% at the end of pregnancy. The weight of the adrenal glands increases from 13 gm. in nonpregnant women to 18 gm. in the latter period of pregnancy, and the excretion of 17-ketosteroids is reduced in patients with toxicosis. The estrogenic hormone content decreases as the severity of the toxicosis increases. The placenta shows no changes that are typical for toxicosis.

Unilateral Hemorrhage of the Adrenals.—At the Feb. 16 meeting of the Austrian Urologic Society, Dr. Pecherstorfer presented the history of a 58-year-old man who at the time of hospitalization experienced blood pressure crises, with a systolic pressure far in excess of 200 mm. Hg. A thorough examination revealed anxiety, attacks of profuse sweating, and signs of collapse. Air-filling and retrograde pyelography of the right kidney revealed a moderate displacement and suggested the possibility of a space-limiting process above the right kidney. An exploratory operation revealed a moderately enlarged adrenal gland, with a bulbar enlargement in the center. The adrenal gland was removed, and a cavity the size of a cherry, which was filled with old blood coagula, was found. A diagnosis of pheochromocytoma was made. The macroscopic findings were corroborated by the histological examination. The patient was free from complaints after the operation, and several subsequent examinations disclosed nothing abnormal. The speaker emphasized the fact that in every patient with obscure hypertension, no matter whether the hypertension is intermittent or permanent, it is advisable to determine the catecholamine content of the urine. This is particularly important if hypertension develops in young persons.

DENMARK

Census of Mental Patients.—In March, 1952, the Danish government appointed a committee of experts to investigate the conditions likely to influence the evolution of mental hospitals in the future. It was suggested that a scrutiny of the sort of patients being treated in a typical mental hospital would give a clue to the likely composition of mental hospitals in the future. A member of this committee, Prof. E. Strömgren, has reported in *Ugeskrift for læger* for Feb. 24, 1955, on the 837 patients in one mental hospital. Dementia paralytica accounted for only 2.6% of these patients, senile and arteriosclerotic psychoses for 7%, epilepsy for 1.3%, schizophrenia for 52%, manic depressive psychoses for 18%, psychogenic psychoses for 6%, neuroses for 2%, and alcoholism for 1.3%. Strömgren concludes that the proportion with dementia paralytica, psychogenic psychoses, and alcoholism will in the future decline even further. Even with the potentialities of modern psychiatric treatment in mind, however, the forces tending to increase the demand for hospital beds will greatly exceed the forces tending to diminish this demand. The same committee has also scrutinized the occupants of the medical wards of two general hospitals to ascertain the amount and nature of the psychiatric problems to be found in such hospitals. Of the 264 consecutive admissions in each of these general hospitals who were examined by a psychiatrist, 5.3% were found to have psychoses, 25.4%, neuroses or psychopathy, and 2.5%, mental deficiency. About one-quarter of all these patients needed special psychiatric care. Another investigation by the same committee was undertaken with 21 medical practices and a total of about 17,000 doctor-patient contacts. Psychiatric problems were involved in 22% of those contacts, which probably occupied between 30 and 50% of the working hours of the practitioners.

Congenital Heart Disease.—In the last 10 years a large portion of all patients with congenital heart disease in Denmark has passed through the cardiological laboratory of medical department B of the Rigshospital in Copenhagen. In a preliminary communication on the subject in *Ugeskrift for læger* for March 3, 1955, Prof. Erik Warburg has reviewed his findings concerning 1,000 patients examined for congenital heart disease in this laboratory between the end of 1946 and Sept. 2, 1954. Nearly 100 of these patients had systolic murmurs of doubtful origin. They were sent to the laboratory for observation for congenital heart disease and often presented no other tangible evidence of it. In 875 patients catheterization of the heart was undertaken, an examination that could be dispensed with when such conditions as persistent ductus arteriosus and coarctation of aorta could easily be diagnosed by other means. Catheterization of the heart caused no death nor permanent disability, but 56 patients responded to this test with a temperature over 100.4 F. As many as 379 patients were more than 15 years old when examined, and 38 were over 40. Persistent ductus arteriosus and septal defects of the auricle were much more common in women than in men, whereas coarctation of aorta was more common in men. Warburg compared his 1,000 clinical cases with Maud Abbott's 1,000 postmortem cases. Warburg found transposition of the truncus arteriosus in only 2 patients, whereas Maud Abbott found 69 such cases; Warburg's 94 patients with systolic murmur of doubtful origin had no counterpart in the postmortem material; and Warburg's patients with persistent ductus arteriosus outnumbered Maud Abbott's in the ratio of 222 to 105. The figures for Eisenmenger's syndrome showed greater conformity, with 43 such cases in Warburg's material and 37 in Maud Abbott's.

Treatment of the Rheumatic Diseases.—Several recent articles in the Danish medical press have emphasized the tantalizing character of phenylbutazone, which is at the same time remarkably effective and very dangerous. The latest article on this subject by Tophöj and his co-workers (*Ugeskrift for læger*, March 31, 1955) reports their experiences with 78 patients given phenylbutazone according to the following dosage: on the first day 800 mg. and on the following days 200 mg. daily (in a few patients 200 mg. on alternate days). With a daily maintenance dose of 200 mg., a constant blood concentration of 5 mg. pe
100 ml. was established. The drug was discontinued when i
effected no improvement in the course of a week. Of the 2
patients with arthritis deformans (including 12 of pure hi
arthrosis), 7 showed no response after a week. The remainin
19 responded well while in hospital, and among them wer
several who continued treatment after discharge. The best re
sults were obtained in seven patients with gout. On the othe
hand, only 6 of 29 patients with rheumatoid arthritis wer
benefited by this treatment. Of the 12 patients suffering fro
side-effects, 7 had to discontinue the treatment on this accoun
The drug should therefore be reserved for certain patients wi
severe disease proving refractory to other methods. The patie
must be informed of the risks in order to gain his cooperati
in making blood tests. The authors hope that the small dos
given in this series have appreciably reduced the risk of sid
reactions without a corresponding reduction of the therapeu
effect of the drug.

ENGLAND

Congress of Ophthalmologic Society.—At the annual meeti
of the British Ophthalmological Society in April, Mr. G. Morg
stressed the permanent visual disability caused by thrombosis
the retinal vein. In other parts of the body the principal fac
leading to thrombosis is slowing of the blood stream, but in
eye the veins are affected more as a result of involvement of
adventitia than as a result of stagnation. Vasodilators that w
formerly used in treatment have been replaced by anticoagula
which are also used prophylactically. To be of value a
coagulants should be given when a retinal vein is found to
dilated, when extravasation of blood is minimal, and while vis
acuity is still good.

Mr. H. B. Stallard said that air had been injected intraocul
for the treatment of tuberculous iritis and diagnosticaly in
location of intraocular foreign bodies and intraorbital neoplas
After cataract extraction air is injected into the anterior cham
to re-form this and to keep the iris and vitreous face away f
the wound. After cyclodialysis for glaucoma, air controls h
orrhage, reforms the anterior chamber, and keeps the fistul
tract open; after operation for retinal detachment, air in
vitreous humor restores the normal anatomic position of

tina and keeps the bed of the transplant away from the iris d lens in keratoplasty. Air, being compressible, produces a ring-like pressure. Its position in the eye is controlled by sture, and it is absorbed within four to eight days. It may use air embolism and glaucoma, but these risks are negligible. erile air may be injected from a syringe autoclaved with the unger withdrawn.

Mr. Anthony Palin and Dr. R. C. Tudway said that it was often fficult to tell the difference clinically between malignant and nmalignant intraocular growths but that actively growing mor tissue takes up radioactive isotopes such as P^{32} more adily than normal tissue does. They have used this isotope r the diagnosis of malignant intraocular neoplasms. Patients e given a compound containing the equivalent of 1 mc. of the tope in water, and, 24 hours later, Geiger counter readings taken in the various meridians of the affected eye and conls are taken from the symmetrical meridians in the other eye. e error is 15%. The significant difference between the two es is 40% or more. The results do not depend on pigmentation the tumor but on hyperactive cell metabolism. In the acute ge uveitis may give a misleading result. The method as used present is of no diagnostic value in the gliomas of children.

dioactive Isotopes.—At the symposium on radioactive iso- pes in April, Dr. E. Pochin of University College Hospital, ndon, said that the surface of the body could be irradiated by al application of a beta ray emitter, such as radioactive phosrus (P^{32}), which is used for the treatment of superficial skin ions. A solution of a radioactive substance may also be inted directly into the lumen of a hollow viscus or introduced o a rubber bag. Both these methods have been used for irdiating superficial bladder tumors. Another way is to inject colloidal suspension of the isotope into a solid tissue, the lloidal state limiting its absorption. Colloidal gold (Au^{198}) s been used in this manner to irradiate a number of solid mors, and it is used to treat effusions due to malignant growths. jected into the peritoneal cavity, it is deposited on the perineum and can irradiate malignant metastases with beta radians. As these are of low penetrating power, the treatment is ly effective against small secondary deposits. When colloidal dioactive material is injected intravenously, it accumulates in reticuloendothelial system and irradiates those organs conining a high proportion of reticuloendothelial cells. This thod has been used in the treatment of the reticuloses and imary tumors of the liver. Larger particles of 30 to 50 μ hen injected intravenously are held up in the lung capillaries, ere they may irradiate tissue selectively. By use of a cardiac theter, the distribution of the radioisotope can be limited to e lung only. Carbon coated with Au^{198} has been used for is purpose, but there is danger of other organs being subcted to gamma radiation from the gold.

Dr. Pochin discussed the use of radioactive isotopes by what called "metabolic localization." Radioactive elements may be ven in a form in which they can be retained selectively by rtain tissues without undue irradiation of the rest of the dy. The best examples of this are the use of radioactive iodine ^{131}) in the treatment of diseases of the thyroid and P^{32}, in e treatment of polycythemia vera. The thyroid concentrates dine to such an extent that I^{131} can be localized in the gland, hich may then be subjected to several hundred times more irraation than the other tissues of the body. Irradiation of the thyid is a useful alternative to operation or the antithyroid drugs r the treatment of hyperthyroidism and toxic nodular goiter, d it is far simpler for the patient. There is, however, a remote nger that carcinoma may subsequently arise in an area of thyid that has been irradiated but not destroyed, and, although no se has yet occurred in a five year study at University College ospital, it is advisable to limit this kind of treatment for nonalignant thyroid disease to patients past middle age. In malignant disease of the thyroid, irradiation is the treatment of choice there are metastases that can concentrate iodine.

Prof. D. W. Smithers of the Royal Marsden (Cancer) Hospital, ondon, said that the use of colloidal gold in effusions due to coplasms is still experimental and that several years must lapse before it will be possible to pick out the best type of case or treatment. The infiltration of tumors with radioactive material is not without risk, owing to the increase in pressure and the danger of disseminating malignant cells. The use of some radioisotopes has advantages over other methods; for example, tantalum-182 is superior to radon seeds in the treatment of superficial tumors of the bladder, and Au^{198} grains may supersede radon seeds for the treatment of certain tumors. Mr. N. Veall of Guy's Hospital said that diagnostic tests can now be done in smaller hospitals, as the capital expenditure on equipment for the established procedures is no longer very costly. In some of the larger hospitals hundreds of radioiodine tests of thyroid function are made annually.

Health in Northern Ireland.—In June, 1954, the Minister of Health and Local Government in Northern Ireland appointed a committee to inquire into the health services in the country. Its report (Report of the Committee on the Health Services in Northern Ireland, Cmd. 334, London, England, Her Majesty's Stationery Office, H. M. S. O. 1955) states that the principal body in Northern Ireland is the Hospitals Authority, which provides hospital and specialist services throughout the area and whose members are appointed by the Minister. One-third are general practitioners, and one-fourth are appointed in consultation with management committees. The other principal body is the General Health Services Board, which arranges for the provision of general medical and other services and controls medical practice. The system has worked well. The number of hospital beds since the scheme was introduced has increased by 10%, admissions have increased by 40%, laboratories have been built or enlarged, and radiological departments have been provided. Outpatient attendances have increased by 77%. Progress in medical treatment in Northern Ireland during the last few years compares favorably with that in any area of the United Kingdom. Certain improvements such as the bringing of the Hospitals Authority and the General Health Services Board under the authority of the Ministry of Health and Local Government are recommended. It is also suggested that the number of members of the Hospitals Authority be reduced from 27 to 20 and that 5 should be physicians. At present 36 hospital management committees control 67 hospitals. The number of committees could well be reduced. A more equitable distribution of hospital endowments is suggested, at present some hospitals being more heavily endowed than others.

The committee recommends that contracts held by consultants and specialists should be reviewed at regular intervals. Facilities should be afforded to consultants and specialists to keep abreast of the latest developments in medicine by attending teaching hospitals. Part-time appointments of general practitioners to hospitals should be encouraged and opportunities given to hospital physicians to engage in part-time general practice. A young physician should not be forced to choose between a career in hospital or in general practice. The committee has examined the method of payment of general practitioners, but it does not consider that any departure from the present method of paying by capitation fee would present any advantage. The provision of health centers and group practice should be encouraged. The cost of prescriptions is higher than the average for England or Scotland. Figures for individual, area, and provincial costs are to be issued quarterly to practitioners, and it is hoped that this will encourage their cooperation in keeping down costs. Consultants are often to blame for expensive and lavish prescriptions. Physicians have also been accused of lax certification, but, when interviewed by the Ministry, they state that if their standards were more exacting they would lose many of their patients. The committee is perturbed about this and considers that disciplinary measures should be taken in bad cases. It suggests that the British Medical Association should cooperate, with a view to raising the standard of certification.

New Treatment for Barbiturate Poisoning.—Dr. A. Shulman and his co-workers have devised a new method of treating barbiturate intoxication (*Brit. M. J.* 1:1239, 1955). A laryngoscope is first used to assess the pharyngeal and laryngeal reflexes, and, if these are absent, a cuffed tube is inserted and the stomach contents carefully aspirated. Antibiotics are given to prevent the possibility of pneumonia, and a clear airway and adequate oxygenation are insured. Then, two specific barbiturate antagonists are administered. These are ββ-methylethylglutarimide (NP 13) and 2:4-diamino-5-phenylthiazole hydrobromide (DAPT). The former is a more potent agent and shows some chemical resemblance to the barbituric acid ring system, so that it probably acts by competition at the surface of the cell receptors, displacing the barbiturate. DAPT is itself a weak antagonist, but it is claimed to be a good synergist with NP13 and a good respiratory stimulant. Both substances produce a rise in blood pressure and sweating. These drugs are injected by means of two separate syringes into the rubber tubing of an intravenous 5% dextrose drip. Every three minutes, 1 ml. of 1.5% DAPT is injected, followed immediately by 10 ml. of 0.5% NP13. The response of the patient is assessed by noting pulse, respiration, blood pressure, muscle tone, reflexes, laryngeal and pharyngeal reflexes, eye signs, presence of voluntary movement, peripheral circulation, and color and temperature of the skin. The injections are continued until the patient is brought to the "safe state" denoted by a return of muscle tone and reflexes and a return toward normal of pulse rate, respiratory rate, and blood pressure. The treatment generally takes about two hours in a deeply comatose patient. A total dose of 1 gm. of NP13 and 0.3 gm. of DAPT is adequate in most cases of barbiturate poisoning. Once the safe state has been reached, the airway is removed and the patient treated as if recovering from light anesthesia. Spontaneous recovery occurs normally within eight hours. If the patient regresses, more drugs are administered. This method of treatment has the advantages of obviating the need for prolonged endotracheal intubation; minimizing the immediate risk to life and the remote risk associated with possible complications of prolonged barbiturate coma; and reducing to a minimum the nursing of the patient. Forty-one patients with barbiturate poisoning, nine of whom were seriously ill and might have died without treatment, were treated by this method, and only one died.

Cot Standards.—In 1950 and 1951 the British Standards Institution laid down standards for hospital and domestic cots. ne of the specifications dealt with the space between cot bars. n order to make it impossible for a child's head to pass through the bars, it was specified that the space between bars should be 3 to 3.5 in. in hospital cots and not more than 3.7 in. in domestic wooden cots. The difference between the two specifications is due to the fact that metal bars have some degree of flexibility. Since the issuing of these specifications, three fatal accidents and one near fatal one have occurred; in all of these the children had slipped through the cot bars feet first and, as the bars were too close to allow the passage of the child's head, the weight of the body pressed the face into the bedding and caused asphyxiation. Even though these accidents did not occur in cots conforming with the current standards, the Ministry of Health and the Home Office (*Month. Bull. Min. Health* **14**:72, 1955), decided to review the matter, as it looked as if the standard designed to eliminate one type of accident permitted another. The anteroposterior chest and pelvic measurements and head measurements of 1,600 children, aged 6 months to 3 years, were therefore obtained. These showed that cots with bar spacing of 3.5 in. would permit a large proportion of 18-month-old children to pass their hips between the bars, and even 9% of 3-year-old children would pass through. After the hips have passed between the bars the next obstacle would be the chest depth, which would prevent all but about 1% of 12-month-old babies, or 5% of 6-month-old babies, from being able to squeeze through the bars sufficiently far enough for the body to hang by the head. On the basis of these new data the British Standards Institution issued a new standard for children's hospital cots; that is, that the bar spacing should be 2.7 in. to 3 in. with an upward tolerance of 0.06 in. The institution, however, has refused to modify the specification for wooden cots. Therefore, the Ministry of Health and the Home Office have decided that they cannot continue to support the present standard in view of their knowledge that fatal accidents could in certain circumstances occur in cots conforming to it. The British Standards Institution has accordingly been asked to indicate that the support of these departments has been withdrawn.

Human Centrifuge for Aviation Medicine Research.—A new man-carrying centrifuge has been installed at the Royal Air Force Institute of Aviation Medicine at Farnborough. The maximum speed of rotation—54.4 rpm, when the two observation cars (or gondolas) are traveling at 115 miles per hour—can be attained in nine seconds from rest. The radial acceleration is then 30 g. An acceleration of 5 g can be reached in 1.5 seconds. These high speeds will be used only for testing structures. It is not proposed to subject men to greater acceleration than 10 or possibly 15 g in the prone or supine positions. All recording is done electrically, and it is this part of the apparatus that is so unusual. The signals are carried in leads along the arm of the centrifuge into the central pillar. They are then led to the floor above by a system of slip rings in a column above the centrifuge chamber. To include the telecommunication circuits, there are 60 silver slip rings, each with two silver-carbon brushes leading to 30 mercury troughs, and each with a spade-type collector. The slip ring system is so efficient that electroencephalograms and electrocardiograms that involve a maximum strength of only 1 mv. can be recorded without distortion even though they have to be led 50 to 60 ft. before being recorded. In the recording room there is a 12-channel inkwriter, which will be replaced shortly by a 24-channel photographic recorder. There is also a cinecamera in the gondola to photograph the experimental subjects' reactions. It is planned to include cineradiographic recordings of the heart and lungs.

Charges Against Research Council Denied.—In the House of Commons a Member of Parliament asked the Minister of Works whether he was aware that a number of cases of cat stealing on a large scale had recently been brought to the courts and that several people had been convicted for this offense; that these cats had been stolen for sale to medical research laboratories; and that the cost of the defense and the fines had in some cases been paid by the Medical Research Council. The Member of Parliament asked what authority existed for the payment of such expenses out of public funds; how much had been spent on these cases in the last six months; and what action the Minister of Works proposed to take to prevent the recurrence of such incidents. The minister stated that there was no truth in the allegations against the Medical Research Council, despite the testimony of some witnesses.

Celebrations at Royal College of Surgeons.—The Royal College of Surgeons at Edinburgh celebrated the 450th anniversary of its foundation in June. The first "Seal of Cause" of the incorporation of surgeons and barbers of Edinburgh was granted by the town council of Edinburgh, and was ratified by James IV of Scotland. A recently discovered portrait of James IV was on view for the first time during the celebrations. The annual banquet was attended by the Duke of Edinburgh, who was admitted to the honorary fellowship. The Duke of Edinburgh humorously said that, although James IV practiced surgery on members of his household, he had no intention of doing so. The president presented the Duke with a silver replica of a surgeon's bleeding cup.

Lack of Facilities for Treating Alcoholism.—Dr. Pullar-Strecker, the secretary of the Society for the Study of Addiction, deplores the lack of facilities for treating the alcoholic (*Lancet* **1**:1072, 1955). In greater London there are 254 hospitals with about 2,325 outpatient clinics specializing in almost every conceivable ailment. Each year every physician is sent a timetable, complete with map, setting out in detail the specialty, location, address, and hours of attendance of all the clinics; yet not one, serving a population of 8 million, caters to the alcoholic or his relatives. Dr. Pullar-Strecker estimates that 500,000 persons suffer, directly or indirectly, from the repercussions of alcoholism in Britain.

New Organism Resembling Salmonella Schottmülleri.—Since December, 1951, a number of strains of Salmonella similar to S. schottmülleri have reached the *Salmonella* and Central Enteric Reference Laboratories from apparently sporadic cases in widely separated parts of the country. The strains were alike in a number of unusual features: they failed to ferment dulcitol, they were antigenically not typical of S. schottmülleri, and they could not be phage-typed. The associated illnesses resembled food poisoning rather than paratyphoid. The organism had been isolated from 99 persons: 43 had symptoms and 56 were symptomless excreters. The cases occurred in three waves: December, 1951, to February, 1952; March to July, 1953; and March to June, 1954—an unusual seasonal distribution for Salmonella infections in the British Isles. In all three epidemics the patients were widely scattered geographically. An analysis of the clinical features in the 43 patients with symptoms showed that 42 had diarrhea; 5 with blood in the stools and 9 with abdominal pain; 20 had vomiting, and a greater number complained of nausea; and 20 had fever. Other symptoms less often observed were joint pains, headache, and general weakness. Neither splenomegaly nor skin rash was observed. The typical illness was characterized by mild to moderate diarrhea. The onset was usually sudden. The duration of the acute illness was two to four days, but some patients had diarrhea for several weeks. Although no definite evidence was obtained on the incubation period, it is considered to be one to three days rather than the longer period usually associated with paratyphoid. The source of infection was not discovered, although it was assumed that most patients were infected by some article of food. The wide scatter of cases could only be explained by some nationally distributed food, but there was evidence that some cases had a more local origin.

PERU

Reserpine in Hyperkinetic Syndromes.—The use of reserpine in neuropsychiatry is increasing. Dr. J. O. Trelles and his coworkers have used a purified extract of reserpine in the treatment of complex hyperkinetic syndromes and have reported their findings at the meeting of the Peruvian Society of Neuropsychiatry and Legal Medicine in Lima in June. The therapeutic trial was carried out in 16 patients, of whom 7 had choreoathetosic movements; 4 had paralysis agitans; 2 had chorea (ordinary and hereditary chronic progressive with mental deterioration); 2 had infantile encephalopathy (one with hemiballic movements and one with pure athetosic movements of the hand); and one had a cephalic tremor. The age of the patients ranged from 9 months to 59 years. In the acquired cases the duration of the disease was two months to 12 years, and in the congenital it was 5 to 59 years. The drug was given in massive doses of 6 mg. daily or in doses starting with 0.25 mg. daily and increasing according to the patient's tolerance. In general the authors preferred to administer the drug at doses slightly lower than those currently used by other investigators.

Reserpine proved to be a valuable drug in the treatment of the hyperkinetic syndromes. It gives better results than those obtained by any other procedure so far available in the symptomatic treatment of patients suffering from choreal and choreoathetosic movements. All the patients, except those with paralysis agitans, showed a marked diminution of their extrapyramidal movements, but the relief of the dyskinesis was transient, lasting only as long as the drug was given. The younger the patient, the better were the results obtained. In patients whose disease was of short duration, a fair temporary remission of the hyperkinetic manifestations was obtained with relatively small doses of the drug, but in chronic or congenital cases larger doses given over a prolonged period were needed to achieve the same results. On the average, favorable responses were obtained with doses ranging from 3 to 4 mg. daily. The clinical response to the drug occurred after a latent period, which was never less than 4 or more than 15 days. This period does not depend on the mode of administration of the drug, but it seems to be related to the elapsed time between the onset of the neurological disease and the appearance of the dyskinetic syndrome (the longer the latter, the longer is the latent period). Side-effects varied from patient to patient and consisted of headache, dizziness, vomiting, insomnia, and/or irritability when the drug was given parenterally, regardless of the amount of the dose and whether the intravenous route was used. Such untoward effects were observed only with large doses when the oral route was used. These side-reactions usually disappeared either spontaneously or when the dose was reduced. Apart from the inhibitory effects shown by the drug on the extrapyramidal movements, it seems to produce a general subjective amelioration in the patient, probably through its sedative action.

Bartonellosis.—Infection with Bartonella bacilliformis is usually acute and is associated with a poor prognosis. In the endemic regions, however, the natives may suffer from a benign form characterized by a warty eruption (verruga peruana), which appeared to confer a lasting immunity to all forms of the disease. In those who contracted the acute form and died, intercurrent infections rather than the bartonellosis were the cause of death. In *Revista médica peruana* (vol. 25, no. 303, March, 1954) Dr. Héctor Colichón reported his demonstration through serologic methods that the mobile organisms found in patients with bartonellosis who died were generally Salmonella typhimurium organisms. Besides, he found that many patients with bartonellosis complicated with intercurrent infection who survived showed detectable serologic signs of Salmonella infection. The question then arose: at what stage of the bartonellosis does the secondary infection occur. Most observers agreed that it took place in the remission (bartonellosis usually shows a hematic or acute phase, a remission, and an eruptive phase characterized by verruga peruana). Dr. Aldana of the Dos de Mayo Hospital, however, believes that intercurrent infection generally arises during the acute phase of the disease.

Recently Dr. M. Cuadra, of the same hospital, reported in *Revista médica peruana* (vol. 25, no. 307, July, 1954) that salmonellosis may arise in the acute phase, early in the remission, or after 15 or more days have elapsed from the end of the acute phase. Secondary infection early in the remission is by far the most frequent. Dr. Cuadra states also that it is possible, on the basis of laboratory findings, to diagnose with certainty what type of complication is developing. In the early type, fairly large quantities of B. bacilliformis are found in the peripheral blood; blood cultures for Salmonella organisms are positive; and there are signs of severe anemia without evidence of hematic regeneration occurring early in the remission. In the type occurring early in the remission the anemia is severe, but signs of hematic regeneration are present; B. bacilliformis is rare in the peripheral blood; and Salmonella organisms are present. In the late type, no B. bacilliformis is found; Salmonella organisms are present; and the anemia is mild or slight with signs of hematic regeneration. In the patient who survives, Salmonella organisms can only be detected indirectly by means of blood cultures and serologic methods. Salmonellosis superimposed on bartonellosis always represents a serious complication, the mortality rate for which is 90 to 100%. Its main clinical features are sudden onset with chills, fever, sweats, and severe digestive disturbances. The patient appears toxic and usually dies in coma within a few days. Often there is hepatic involvement, which adopts the clinical pattern of a Salmonella hepatitis and shows a high direct bilirubin level. When this complication arises early, its clinical findings are superimposed on that of the bartonellosis, and the diagnosis is much more difficult.

A previously existing severe anemia is necessary for intercurrent infection to develop, and the more severe the anemia, the worse the prognosis. The percentage of patients with bartonellosis in whom the complication of salmonellosis develops is about 40. Bartonellosis appears to invalidate the immunity to salmonellosis that the patient has developed over the years. Other complications, such as tuberculosis, malaria, dysentery, pneumonia, and viral diseases are rare. The broad-spectrum antibiotics, especially chloramphenicol, have greatly improved the prognosis for patients whose bartonellosis is complicated by salmonellosis. Patients with bartonellosis should be given chloramphenicol as early as possible. In Dr. Cuadra's series of 13 patients, the 8 who received the drug early were saved and the others died. Such antibiotics as penicillin, streptomycin, chlortetracycline, oxytetracycline, tetracycline (Achromycin), and erythromycin have proved to be useless in the control of salmonellosis, although they do check the bartonellosis. Because the salmonellosis is the killer, treatment should be directed against it and not against the bartonellosis.

CORRESPONDENCE

TREATMENT FOR HYPERTENSION

To the Editor:—In his recent article on the treatment of hypertension (*J. A. M. A.* 158:359-367 [June 4] 1955) Dr. Grimson has taken issue with me on two points: (1) the use of neostigmine to overcome constipation produced by the ganglion-blocking agent, and (2) administration of the morning dose of the orally given blocking agent after, not before, breakfast. I have advocated 15 to 30 mg. of neostigmine taken orally on an empty stomach as being generally the most effective method for overcoming the constipating effects of the ganglion-blocking agents, particularly pentolinium. Dr. Grimson, however, has found in anesthetized dogs, rendered hypotensive with pentolinium, that the intravenous injection of neostigmine will result in a rise of blood pressure back to or toward control levels. On the basis of these studies Dr. Grimson concludes that we are producing the same effect in patients. During the past three years we have treated over 100 hypertensive patients with pentolinium using neostigmine orally in the manner already indicated. In the majority of these patients blood pressures were recorded in the hospital during the period of regulation before and two hours after neostigmine. In no case have we observed an escape of blood pressure that could be attributed to the action of neostigmine. In addition, somewhat over 50 patients who have been taking the two agents for one year or longer record their blood pressures at home. They take neostigmine on arising in the morning. After they have dressed and had breakfast they record their blood pressure. Thus, the blood pressure is being recorded one or two hours after administration of the drug. Rather than being higher these pressures usually are the lowest of the day. In some instances I have asked the patients to check their blood pressure immediately following the bowel movement, usually occurring approximately an hour after neostigmine is taken, that is, at the time of maximum action of the neostigmine. A sudden upsurge of blood pressure never has been noted at this time. The pressures recorded at these times in the morning almost always have been as low as any recorded during the day.

A sizeable collection of data, therefore, lends no support to Dr. Grimson's contention that by giving neostigmine to our patients we are reversing the hypotensive effects of the ganglion-blocking agent. Neostigmine has parasympathomimetic (muscarinic) and ganglion-stimulating or ganglion-depressing (nicotinic) effects. Dr. Grimson apparently has observed the nicotinic effects of the drug in anesthetized dogs while we have observed only the muscarinic and never the nicotinic effects in patients. It should be pointed out that the species are different, the routes of administration different, the blood concentrations probably different, and the experimental condition (anesthetized versus nonanesthetized) different. It is not surprising, therefore, that the results are different. These considerations are more than academic. Our patients would complain loudly if neostigmine was taken away from them. Any measure that eases the unpleasant side-effects of the ganglion-blocking agents is too valuable to be discarded because of some animal experiments that may not be pertinent to the issue at hand.

Dr. Grimson's second criticism is directed toward my recommendation that the morning dose of pentolinium be taken after, rather than before, breakfast. He states that the pharmaceutical concern that manufactures pentolinium quotes me to this effect. This is true. He further states that in the original communication of our group concerning pentolinium we advised that the dose be given before breakfast. This, also, is true. However, we since have changed our opinion. Dr. Grimson believes that pentolinium exerts a greater hypertensive effect if it is given before meals. I agree with this completely. What then is the reason for my seemingly inconsistent recommendations? It was several of our more observant patients who taught us to give the first dose after, rather than before, breakfast. By recording their blood pressures at home they noticed that their sensitivity to the hypotensive effects of pentolinium was greatest on arising in the morning and decreased progressively during the remainder of the day. Postural hypotension usually was present on arising, before the morning dose was taken, due to residual pentolinium taken the previous night. Since we utilized an eight-hour dosage interval it was necessary for us to administer a dose in the morning sufficiently large to maintain a reduction of blood pressure until 2 or 3 p. m. However, when a dose this large was taken before breakfast, absorption was accelerated and excessive hypotension occurred one or two hours later due to the increased susceptibility of the patient to postural hypotension during the morning hours. As a result, the patients who were attempting to earn a living encountered syncopal episodes on the way to or at work, or if not, experienced unpleasant faintness and difficulty in mental concentration. Nevertheless, by 2 p. m. they again were quite hypertensive.

Some of these patients solved this problem by taking th morning dose on a full, rather than an empty, stomach. As th early morning hypotension disappeared the pentolinium bega to exert its effects more gradually and a more even reductio of blood pressure from early morning to 2 p. m. resulted. Th diurnal fluctuation of responsiveness or sensitivity to pentoliniu or other ganglion-blocking agents is a vital consideration i dosage adjustment. Its importance is not appreciated unles blood pressures are recorded at home. In order to obtain a fairl even reduction of blood pressure, the afternoon dose frequentl must be larger than the morning dose, in some instances as muc as four times the morning dose.

COBALT AND THYROID DYSFUNCTION

To the Editor:—An article by J. P. Kriss and co-workers (T JOURNAL, Jan. 8, 1955, page 117) stated that myxedema a goiter may result from cobaltous chloride medication. We cently obtained data that further indicate that cobalt medicati may result in thyroid dysfunction. A 19-year-old man with sick cell anemia was given 100 mg. of analyzed cobaltous chlori in an aqueous solution three times a day for 44 days. The pr tein bound iodine and cholesterol concentrations of plasma d not change significantly, nor was a change in the size of t thyroid gland noted. However, a radioiodine uptake before cob treatment was 40%; after 23 days it dropped to 6.4%, and the 39th day it was 3.2%. Seven days and 30 days after thera with cobalt was discontinued the radioiodine uptake was 27 and 43% respectively.

RUPTURE OF AORTIC ANEURYSM INTO ESOPHAG

To the Editor:—In the Correspondence section of THE JOURN June 18, 1955, page 587, Dr. John T. Pewters describes a c of aortic aneurysm with rupture into the esophagus and ref to a letter in THE JOURNAL, Dec. 26, 1953, page 1571, by D Samuel Baer, who questioned the rarity of this occurrence stated by Calenda and Uricchio: "In the past 27 years on five such cases have been described in the world literatur (*J. A. M. A.* **153**:548 [Oct. 10] 1953). I also published such case recently (Krudy, A. G., and Smith, J. A.: Multiple Saccul Aneurysms of the Thoracic Aorta with Spontaneous Ruptu Into the Esophagus: Report of a Case, *Dis. Chest* **27**:690, 19 and reviewing some earlier studies on large series of aor aneurysms found that rupture into the esophagus was not ra Of 233 cases of aneurysm of the thoracic aorta report by Lucke and Rea (*J. A. M. A.* **81**:1167 [Oct. 6] 192 5 perforated into the esophagus. Of 4,000 aneurysms of t thoracic aorta reviewed by Boyd (*Am. J. M. Sc.* **168**:625, 192 112 ruptured into the esophagus, and of 633 cases of saccul aneurysms of the thoracic aorta reported by Kampmeier (*An Int. Med.* **12**:624, *1938*) the most frequent site of rupture w the esophagus with 20 cases (one ruptured into the esophagus and also into the left pleural cavity). Another case of aortic aneurysm rupturing into the esophagus and into the left pleural cavity was recently reported from the University of Illinois in Diagnostic Problems in THE JOURNAL, page 479, June 11, 1955. The incidence of syphilitic aneurysm and so its rupture into the esophagus might be decreasing because of the more efficient treatment of the early syphilis; however, as the recently published four cases demonstrated, it is still far from being a medical rarity.

PUBLIC RELATIONS

What Is Ahead

Like American industries and businesses, the medical profession in recent years has become aware of the importance of good public relations. How to create and maintain good public relations in medical practice will be the subject of this page, which will appear on a monthly basis. Discussions of the philosophy upon which good public relations is founded will be coupled with actual suggestions from physicians for improving individual relationships between doctors and the public. Subject material will include the public relations aspects of all phases of medical practice as well as some medical society public relations activities requiring cooperation of individual physicians.

Public Relations—Is Everybody an Expert?

Everybody talks about public relations today, but few can define the term specifically. Sometimes it is easier to begin explaining public relations by stating that it is not press agentry and publicity. A California public relations consultant says: "It is not a cover-up for shortcomings; it is not a propaganda campaign to disguise the facts; it is not a cure-all; it is not merely the creation of favorable press comments." Public relations is a way of thinking translated into action. It is not some vague entity, but an actual philosophy that can be applied to medical practice combining public service with efforts to win good will.

What some people fail to realize is that everybody has public relations—it is not a many-colored coat that can be donned at will. The important question is this: do you have good or bad public relations? Dr. Sidney Pratt, past-president of the Montana Medical Association, has pointed out that "public relations covers a wide range of individual and group contacts: Doctor-patient relations; doctor-doctor relations; doctor-hospital relations, other inter-professional relations" and so forth. Where there are people attitudes exist. The sum of the attitudes people harbor about a service, a product, or an individual add up to the kind of public relations that individual or commodity has.

"In an earlier day, every doctor was his own public relations expert, and his failure in the field of public relations injured himself but had little effect upon the profession as a whole," wrote Dr. J. Decherd Guess in the *Journal of the South Carolina Medical Association.* "Such is not the case in these modern times of easy communication and fast travel. One man's failure, or the failure of a small group, is widely publicized and hurts us all. It is my belief that the basis of the antagonism which is directed against us as a group lies not in group relationships with the public, but rather in the individual relationship of the physician with the patient and the patient's family." Thus, public relations is every physician's personal responsibility. Like charity, it begins at home, with a physician's sincere desire to serve his patients to the best of his ability and to provide them with the kind of personalized care each desires.

"A Doctor Who Specializes in Me"

"I want the doctor to show he cares what happens to me," says the patient. "I don't want a cold fish!" Patients want a doctor who regards them as people, not just as interesting cases. A medical school dean recently pointed out that "the gap between doctor and patient, already disturbingly wide, is continually widening." The loss of personal rapport between doctor and patient is responsible for the rising cry for the return of the "good old horse-and-buggy doctor." Few people would entrust their care to him today, for often he had more sympathy than skill to offer. Still, he filled a definite need in his patients' lives, sometimes unmet today. He was combination physician, father-confessor and friend, and a human relations expert.

Impersonal medicine is not good medicine, no matter how scientific. Not all doctors are born extroverts or naturally skilled in the art of human relations, but the right attitude can be developed. Here are some suggestions from practicing physicians to help create a good relationship between doctor and patient:

Give the patient a warm welcome. "Be glad to see patients, even if you are a little tired; be frank, be prompt, never give the impression you are doing the patient a favor. Skill is no substitute for kindness."

Deal sympathetically with patients. "Listen with calm, unhurried and sympathetic attitude to the patient. Kindness and tactfulness are important. It is not easy to be pleasant as one nears the end of a long day, but every patient needs good humor, sympathy and a quiet manner, no matter how weary or upset the physician may be personally."

Don't appear hurried. "The physician should concentrate his entire attention on the patient during the consultation. His desk should be free from distracting material. If possible, he should refrain from answering the telephone while seeing a patient."

Treat patients as individuals. "Patients should receive special handling with reference to age and position. The older man expands in an atmosphere of respect and deference; the aging woman objects to any act that may emphasize her frailty. Adolescent youngsters object to being 'treated like children.' "

Get the patient's name right. "Make sure you know the patient's name before he enters the office—and learn to pronounce it correctly."

Get to know the patient as an individual. "Spend a few moments in conversation about the patient's interests. Let him talk about himself."

Place yourself on the patient's level. "Don't talk down to him. Contrive somehow to cultivate a non-medical vocabulary. Beware the Jehovah complex."

Friendliness, sincerity, tolerance, frankness, patience, gentleness—these are the qualities that the patient seeks in his doctor. A Kansas City *Star* columnist says: "I judge the medical profession by my doctor. When I go to him, I want to go as a person in whom he is interested rather than as a name on a filing card. I need his interest, his sympathy as much as I do his medical skill. I am not speaking here for a soggy bedside manner. I am speaking for warm sympathy."

"The art and the science of medicine must be blended in proper proportions and applied judiciously to the human being. This is good medicine."

PRoblem Corner

The doctor asks: "A local newspaper reporter has asked me to give him a story concerning local opinion about a new medical discovery. Is it ethical for me to cooperate with him or shall I refuse the information?"

Generally, the physician should cooperate with the science writer. If the story is of interest to the public, it should be told accurately. Times have changed insofar as release of newsworthy material by physicians to the press is concerned. Doctors are shedding their traditional reluctance and meeting with reporters to provide them with authoritative information on health and medical subjects.

This changed attitude has come about as a result of a revision in the Principles of Medical Ethics. Section 5 on the Relationship of the Physician to Media of Public Information now clearly states that: "The medical profession considers it ethical for a physician to meet the request of a component or constituent medical society to write, act or speak for general readers or audiences." The code states that physicians may provide information regarding important medical and public health matters that have been discussed during open medical meetings or in technical papers that have been published. Information regarding a patient's physical condition also may be released if the patient gives his permission; however, in both instances, the physician is advised to seek the guidance of appropriate society officials.

Many medical societies, in order to establish orderly procedures for providing information to the press on medical subjects have designated official spokesmen. Others have developed codes of cooperation that spell out responsibilities of physicians, hospitals, and press representatives in the three-way relationship. In every code of this type, it is clearly stated that "the primary responsibility of the doctor and the hospital is the welfare of the patient."

What happens when authoritative information on a medical news story is not provided has been forcefully demonstrated during recent months in coverage of the poliomyelitis vaccine story. No medical organization received advance information; physicians consequently were without valid reports on the merit of the vaccine. A barrage of conflicting stories appeared in the press. Confusion and fear were generated, and the entire poliomyelitis program threatened. In cities all over the country just the opposite thing happened a year earlier when physicians were asked to cooperate in the experimental poliomyelitis vaccine program. Medical societies, armed with the necessary information, were able to go to the newspapers, present the facts, and inform the public of the need for their cooperation. Fears were dispelled, and the program proceeded with great success. Mutual understanding between doctors and newsmen helps both groups promote the public welfare and render the public services to which the medical profession and the press are dedicated.

BUSINESS PRACTICE

ROLE OF THE LIFE INSURANCE TRUST IN ESTATE PLANNING

John R. Golden, Chicago

It is unfortunate but nonetheless true that family obligations are usually greatest when savings are relatively small or nonexistent. A man with a wife and small children is justifiably concerned with the future welfare of his family should his death occur before his estate has grown to a respectable size. The dilemma of how to provide the greatest family protection when resources are limited can be solved, at least partially, through the purchase of life insurance; but life insurance, of itself, cannot provide the type of family security most often desired.

As a rule, the first policies purchased will present no problem. Most likely they will be modest in amount and there will be no hesitancy in having them payable outright to the wife. But as the young man prospers and his insurance program gathers momentum, he is likely to become concerned at the prospect of having a substantial sum payable outright to his wife at his death. He may well have some misgivings as to whether or not her limited experience in financial matters will enable her to invest it prudently. Also, can he be certain that she will have the firmness to resist the entreaties of needy relatives and the importunities of eager salesmen? And will she have the innate wisdom to use the insurance proceeds in the best interests of herself and the children? Most men have confidence in the ability of their wives to cope with these problems but, if given any reasonable alternative, would prefer not to put them to the test.

Partly for this reason insurance companies permit the insured to direct in advance that in lieu of a lump-sum payment the proceeds shall be paid out in any one of a number of ways specified in the policy. The exact settlement options that may be selected will vary with each company, but the following are typical of those most widely used.

1. *Proceeds Held at Interest.*—Under this option the proceeds are retained by the company, which pays interest thereon to the primary beneficiary for life and the principal sum to the estate of the beneficiary or to other named persons, if desired. The company usually guarantees that such interest payments will not be less than a certain specified rate.

2. *Proceeds Payable in Installments.*—Under this option specific amounts for each $1,000 of face value of insurance will be paid monthly for any selected period varying from 1 to 30 years.

3. *Life Annuity.*—This option will provide equal monthly payments of a specific amount for each $1,000 of face value of insurance (depending upon the then attained age of the beneficiary) for the remaining lifetime of the beneficiary. In consideration of smaller annuity payments, the companies will guarantee to continue payments for a specified time, such as for 5, 10, or 20 years. Thus, after the death of the primary beneficiary, payments would be made to a secondary beneficiary until the expiration of the period selected.

4. *Income of Specified Amounts.*—Payments of a specified amount will be made periodically until the proceeds with interest credited annually at a guaranteed rate have been exhausted.

Through the use of some one or more of the above options, or other similar options that may be permitted under the terms of the particular policies, a husband can exercise considerable control over the manner in which the proceeds of his life insurance will be applied for his family's benefit. But in many cases, particularly where minor children may be involved, even these optional methods of payment will be much too limited.

The chances are that a young man who has embarked upon an insurance program to provide against the eventuality of his death has given little thought as to the exact manner in which the insurance proceeds will be used to benefit his family. If asked the question directly, he might express the hope that the funds would permit his family to continue living on much the same basis as during his lifetime. By that he means that if some member of his family is involved in an accident or is suddenly taken ill, he wants funds made available to cover the emergency; or if his son shows special aptitude in medicine, engineering, or law, he wants to go all out to help further his education. But insurance options do not readily lend themselves to such objectives. The insurance companies agree to pay out the funds in accordance with a fixed and predetermined plan and ordinarily no variations can be made to meet an unforeseen emergency or family crisis.

The chief objection to reliance upon optional settlements as the means for carrying out an estate plan is the lack of flexibility that they permit. This should not in any way be regarded as a reflection upon the insurance companies. It is the primary function of insurance to provide funds at the death of the insured; and the willingness of insurance companies to pay out the proceeds in several optional ways should be regarded as an additional service they are willing to perform. But if settlement options are too restrictive to give the degree of flexibility usually desired in a carefully considered estate plan, what alternative is available? One answer, of course, is the insurance trust.

Just what is an insurance trust? To many persons a trust of any kind is something mysterious and formidable that might be perfectly all right for others but is much too involved and complicated for them. To more and more people each year, however, the advantages of the trust arrangement as a means for the holding, management, and ultimate distribution of property are being recognized. Stripped of all technicalities, an insurance trust is a written agreement between the person making the trust and the trustee (usually a trust company) whereby the maker agrees to name the trustee as beneficiary of certain policies upon his life, and the trustee agrees to collect such insurance policies upon the maker's death, invest the proceeds and distribute the income and ultimately the principal, in accordance with the instructions set forth in the trust agreement.

Reliance upon insurance options to carry out an estate plan is much like buying a suit of clothes through a mail order catalog. The material might be excellent, but it can hardly be expected to fit as well as though it had been tailored to meet your individual measurements. In general, it can be said that the "fit" of your insurance trust is limited only by your own wishes and the skill of your attorney in drafting adequate provisions for the trust agreement. In order to appreciate the great

---

Trust Counsel, Harris Trust and Savings Bank.

ibility in estate planning that can be achieved through use the insurance trust, it may be helpful to consider a more or typical example.

Mr. Thompson is 40 years of age, is married, and has three ldren ranging in age from 5 to 17 years. His annual income ow relatively high but up to the present he has been able to ld only a modest estate, consisting principally of his home, ch is now free of debt, and savings of a few thousand dollars. addition to this, he has taken out insurance over the years now amounts to $60,000.

t the present time, Mr. Thompson's insurance is payable is wife under options that will pay her an annuity for life, in the event she survives him by less than 20 years the xpended portion will be paid equally to his children. In the nt of his death at this time, Mrs. Thompson would receive fe annuity of approximately $200 per month.

fr. Thompson realizes the inadequacy of this amount to perly provide for his family in the event of his death but faith in the ability of his wife to cope with the normal blems that might be expected to arise. Of late, however, he become increasingly disturbed by these thoughts. 1. Would cient funds be available to meet an emergency? Mary, his ngest child, has been in frail health and might require special in the future. Also, what might happen if an accident should ll his wife or one of his children? 2. Suppose his wife uld become legally incompetent? The insurance company ld, of course, insist upon making payments to her conator appointed by the court. Or suppose that his wife did become legally incompetent but because of illness or accident unable to manage her affairs or look after the children? Or even worse, what might happen if his wife, also, should before the children were grown? His older son, Dick, has been graduated from high school and is about to enter ege. If all should go well for Mr. Thompson, a few more rs would see Dick well through his schooling and possibly ted upon his own career. His younger son, Paul, however, ust starting in grade school and his entire schooling lies re him. Suppose that at the time of his wife's death $30,000 his insurance still remains with the company. Under the on selected one-third of this amount would be paid to each is children. But would he be treating them all fairly? To k, if he had by then completed his education, the inheritance ht be a windfall. But what about Paul and Mary? The sum ld hardly seem adequate to give them the same start in life he had been able to provide for Dick.

eeply concerned over the very evident shortcomings of his te arrangements, Mr. Thompson sought the advice of his rney, his insurance agent, and a trust officer of his local k. After careful analysis of Mr. Thompson's financial rerces and thoughtful consideration of his objectives, they ised him that the only practical way to achieve anything roaching the flexibility he had in mind would be through operation of a trust.

fr. Black, his attorney, suggested two alternative ways for ating the necessary trust arrangement. One, by incorporating necessary trust provisions as a part of Mr. Thompson's last l; the other, by creating an insurance trust. Either approach ld give Mr. Thompson the flexibility he desired. However, the following reasons Mr. Black recommended that his client ablish an insurance trust.

. *Protection Against Creditors.*—In order to create a trust ler will, it would be necessary for Mr. Thompson to make his ate the beneficiary of his insurance policies. This would sub the proceeds to the claims of creditors of his estate. Making policies payable to the trustee of an insurance trust would have this effect.

. *Reduced Probate Expense.*—Attorney's fees and executor's nmissions are normally based upon the value of the estate sing through probate. Use of the insurance trust would keep se funds out of the probate estate and tend to minimize these sts.

3. *Savings in Inheritance Taxes.*—In Illinois and many other tes insurance proceeds that are payable to the estate are sub t to inheritance taxes. Insurance proceeds that are payable a named beneficiary or to a trustee under an insurance trust e generally exempt from state inheritances taxes.

As a result of their discussions, Mr. Black drafted an insurance trust agreement with a trust company as trustee. It included the following provisions that were of particular interest to Mr. Thompson.

1. *Payments During Lifetime of Mrs. Thompson.*—The trustee is directed to pay the entire net income earned from investment of the insurance proceeds to Mrs. Thompson in monthly payments. If the income should not be sufficient to meet the normal needs of Mrs. Thompson and any of the children who might be dependent upon her, or to meet any emergency such as unforeseen illness or accident, the trustee is directed to pay from principal of the trust sufficient funds for such purposes.

2. *Payments After Death of Mrs. Thompson.*—After Mrs. Thompson's death (or after Mr. Thompson's death if his wife should die before him or at the same time), the trustee is directed to hold the trust property as a single fund for the benefit of the children as a group. The instrument clearly states Mr. Thompson's desire that it be used for the primary purpose of affording substantially equal educational opportunities for each of his children and to defray, in whole or in part, the extraordinary expenses resulting from accident, illness, or infirmity. The trustee is given the right to use its discretion in making payments to or for the benefit of any one or more of the children.

3. *Distribution upon Termination.*—The trust is to terminate at the death of Mrs. Thompson or when the youngest surviving child attains age 21, whichever event should last occur. At that time the trustee is directed to divide the trust estate then remaining equally among the children. Should any child have died before that time leaving descendants, the deceased child's share would be distributed among such descendants. However, instead of making distribution outright to any minor descendant, which would necessitate the appointment of a guardian by the court, the trustee is authorized to hold the share of such minor until he or she attains legal age and until then to use it for the benefit of such minor.

The greater degree of flexibility permitted by an insurance trust over optional settlements was the principal feature that interested Mr. Thompson. It is not, however, its only role in estate planning. In larger estates, where liquidity is important for the payment of death taxes, insurance is frequently taken out for this purpose. In many of these cases the wife is named as beneficiary with the expectation that she will contribute from the insurance proceeds whatever funds are needed to pay taxes and other cash requirements.

There is, of course, no legal obligation for a wife to use the funds for this purpose, but a husband will not usually be greatly concerned over the possibility that his wife will fail or refuse to do so. Suppose, though, that she should die shortly after him and before she could make the funds available to his executor? Or, suppose that she should become incompetent? The executor of her estate or conservator appointed by the court would have no authority to use the insurance proceeds to furnish liquidity in her husband's estate.

Assume, however, that the wife collects the insurance and does turn over to the executor sufficient cash to pay all death taxes. Unless handled properly, this might well result in her having made a taxable gift to her husband's estate.

On the other hand, making the insurance payable to the husband's estate would needlessly subject the proceeds to the claims of creditors and to state inheritance taxes. Through use of the insurance trust, these objections can be eliminated while at the same time assuring that the funds will be available to furnish liquidity, if needed.

In more and more instances the insurance trust is becoming the basic instrument in estate planning. The provisions of the trust agreement are usually drafted in such manner as to direct the trustee in the investment, management, and distribution not only of the initial policies of insurance made payable to it as beneficiary but also of any additional policies made payable to it thereafter, as well as any property devised or bequeathed to it by the settlor or any other person.

This is how it operates. In the case of Mr. Thompson, his assets other than his insurance consist only of his residence and a small amount of savings. In this instance, because the value of the property involved is not great, he may decide to leave it outright to his wife and will so provide in his last will. However, if the property were greater in value, Mr. Thompson might leave it to the trustee of his insurance trust to be administered under the terms of that instrument. Mrs. Thompson, also, will execute a simple will. Her property, if any, will normally be left outright to her husband if he survives her, otherwise to the trustee of his insurance trust. Thus, after the deaths of both Mr. and Mrs. Thompson, the insurance proceeds as well as the separate property of each of them will be consolidated into a single trust for the benefit of their children.

The insurance trust, or for that matter other types of living trust as well, may serve an entirely different but equally important function in estate planning. Quite often upon retirement from active work, a man and his wife may move to another state where the climate and living conditions are more suitable to their new mode of life. Children, grandchildren, friends, and business associates are left behind. Very likely they have already worked out an arrangement for the distribution of their estates. Let us say that they have both made wills, creating trusts for the benefit of children and grandchildren and naming their local trust company as trustee. With the bulk of their assets located in the original state and perhaps the majority of their immediate family living there as well, it is probable that our retired couple would prefer to have their estate arrangements carried into effect by the bank or trust company with which they have been doing business for many years. But what effect will their change in residence have upon their estate plans?

The laws of many states prohibit trust companies located in other states from acting as testamentary trustees. It is possible, therefore, that the original trust company could not act in behalf of its customers if they should die residents of another state. However, state laws cannot prevent the establishment or interfere with the operation of trusts outside their jurisdiction. Thus, if an insurance or other type of living trust has been established with the local trust company as trustee, a later change in legal residence will have no effect upon its operation. In addition, the laws of many states that prohibit a foreign trust company from acting as testamentary trustee do not prevent property from being added by means of a will to an existing living trust even though the trustee is located in another state. Therefore, through the use of the living trust, our retired couple can be certain that their estate arrangements will be carried out by a trustee of their choice.

A final role of the insurance or other living trust is to assure privacy. A will offered for probate becomes a public document and can be examined by anyone interested or curious enough to do so. A person who is prominent or who lives in a small community may hesitate to have his personal family arrangements spread on record as a public document. The trust agreement, on the other hand, is a private undertaking between the settlor and the trustee, and its provisions are not open to public gaze.

115 W. Monroe St. (90).

MEDICAL FILM REVIEWS

Health: Your Clothing: 16 mm., black and white, sound, showing time 11 minutes. Technical supervisor: Dr. Dorothy Nyswander, University of California School of Public Health. Produced in 1953 by Centron Corporation for and procurable on purchase ($50) from Young America Films, 18 E. 41st St., New York 17, or on rental from state and local film libraries.

The purpose of this film is to promote a better understanding of the function, proper selection, and care of personal clothing and footwear. It deals with the function of clothing as protection for the human body, the importance of choosing clothing appropriate to the weather, and the "how and why" of caring for personal clothing. It emphasizes the effects of proper clothing on health and also points out esthetic values; however, the scenes about children calling attention to spots on their clothing are a little unrealistic. This film covers the subject adequately and should be helpful as a teaching aid for intermediate grades.

BUREAU OF INVESTIGATION

A CHICAGO CHIROPODIST IN HAWAIIAN HOT WATER

Anthony M. Senese of Chicago; Tucson, Ariz.; late of Hawa and now address unknown, is a chiropodist with medical ar bitions. He is an outstanding example of those few imposto who seem to be able to function adequately as interns or re dents in large hospitals. Outside the hospitals, however, th sooner or later run into grief. Inevitably the lack of form training shows up. The latest medical activity of Mr. Senese w reported in a special "Members' Letter" issued by the Bett Business Bureau of Honolulu, Hawaii, April 4, 1955. Sene had pleaded guilty to practicing medicine without a valid ter torial license. He was assessed a fine of $250, with $150 mitted on condition that he leave Hawaii within one week. Th he did. Senese has shown little regard for facts in filling o applications for membership in a scientific society or for e ployment in medical institutions. His ingenuity has made ne essary a careful check of his background. The following is chronicle of Mr. Senese's career, based on data in the files the Bureau of Investigation.

"MEDICAL" BACKGROUND

In applying for membership in a prominent scientific orga zation in 1946, Senese represented that he was born in Chica in 1912, graduated from a Chicago high school in 1930, ceived the degree of bachelor of science from the National C lege of Canada in 1934 and obtained the degree of doctor medicine from the Illinois College of Physicians and Surgeo Chicago, in 1938. He also claimed to have been a health offi for the Chicago Board of Education, and to have been engag in "research." The Better Business Bureau of Honolulu repo that official records show that Senese was born in Italy in 19 and was brought to Chicago as a child. The Chicago Board Education states that he graduated from McKinley High Sch in 1931. The claim of a bachelor of science degree from t National College of Canada in 1934 presumably refers to o of the enterprises of Earl Anglin James, who has more degr and accomplishments, according to his own admissions, th the proverbial dog has fleas. The course of study in Jam "institution," if any, would not meet curriculum requireme of any accredited university.

With respect to the claimed degree from the Illinois Colle of Physicians and Surgeons, Senese could not have gained a mittance to medical licensure examination on such a diplon This school (if one can call it that) was said to have be operated by persons then affiliated with the National Colle of Chiropractic, Chicago. In 1933 an Illinois court hand down a decision that refused to "graduates" the privilege taking examinations for medical licensure in Illinois. Conte porary news accounts describe the school as a "one-room c lege," with officers who "doubled in brass" as directo professors, and students. As to the claim that he had forme been "Health Officer, for the Board of Education of City Chicago (Investigator for 350 schools) under National Defe Program—also Health Officer for Civilian Defense of City Chicago," Senese undoubtedly referred to his having been e ployed by the Chicago Board of Education from 1940 unt 1944 as an assistant office secretary and subsequently as a investigator for the law department of the board (as a politic appointee). As for the "research," Senese was connected in som manner with the Iodine Research Institute of Chicago, operate by Dr. William C. McGregor, a combination physician an osteopath, and others. Actually, this was a "patent medicine enterprise. As a result of his activity, McGregor was later (194 convicted of violation of the Federal Food, Drug, and Cosmeti Act for misbranding his iodine preparations. The applicatio for membership in the society mentioned earlier apparently wa accepted but was challenged in 1948. The membership cease shortly thereafter, in the wake of an inquiry to the Bureau o Investigation.

The facts are that Senese enrolled at the Chicago College of Chiropody in January, 1932, and was admitted to the junior class on the basis of previous work allegedly done at a Chicago chiropody clinic for three months in 1931. He received the degree of doctor of surgical chiropody on June 7, 1933. The state of Illinois licensed him as a chiropodist on Jan. 29, 1934, and this license was renewed annually for the next six years. The Illinois Department of Registration and Education advises the Bureau that the license is no longer in effect. Senese was listed as a chiropodist in Chicago telephone directories from 1934 to 1942 and is described by other occupants of the building in which he had offices as having been there full time.

Senese was licensed as a naturopath in Arizona in 1935. The Arizona Board of Medical Examiners has pried out of its naturopathic counterpart the fact that such license was issued on the basis of a letter from the "Polytechnic College of Natural Therapeutics," Fort Wayne, Ind., certifying Senese's attendance for a "full four-year course" ending in June, 1935. In 1946 Senese wrote to the Arizona Basic Science Board from Chicago, as "N.D.," seeking a certificate under the "grandfather" clause. In December of that year his naturopathic license was reinstated.

Apparently naturopath Senese did not confine his Arizona "practice" entirely within the limits of "natural" healing. The Tucson Better Business Bureau has reported that in August, 1948 he was arrested on a charge of illegal medical practice. He pleaded not guilty, and trial was set for November, 1948. There is no record that Senese appeared for trial. The charge was dismissed in 1952.

"MEDICAL" CAREER

About 1948 Senese apparently dropped the naturopathic field to return to the attempted practice of medicine. In that year he filed his first application for admission to the Illinois medical licensure examinations. This was denied because of lack of complete records of his medical studies and lack of proof of an approved internship.

Senese then began negotiations with a reputable Chicago hospital for an appointment as an intern. In his application to the hospital, Senese claimed graduation from the "Universidad Libre Mexicana, Mexico City." His diploma was dated 1939. Translated freely, it read: "The Free Mexican University: Due to the scientific merits and moral virtues of Mr. Anthony M. Senese, M.D., with all solemnity bestows the degree of Doctor in Medicine of this Institution. 'For Humanity and Science.'" Also submitted was a transcript that alleged completion of a six-year medical course. The diploma and the transcript were signed by "El Rector F. Rodriguez Toriello" and "Secretary C. Espinosa T." They bore the seal of a Mexican notary public that was authenticated by the American consul in Mexico City. Curiously, the "transcript" included this notation: "This document was issued at the request of the interested party in the City of Mexico, D.F., on the 10th of October, 1939." But the notarization and authentication were not obtained until September, 1950. A diploma from this alleged Mexican school was actually of no greater value than that of his first claimed "Illinois College of Physicians and Surgeons." The Consul of Mexico, in a letter to the Bureau of Investigation, said in part: "We have received statement from the Secretaria de Educacion Publica (Public Education Department) that in Mexico there is not a University by the name 'Universidad Libre Mexicana.' In other words, as does not exist such University, the Mexican Government do not recognize any title issued by said 'Universidad Libre Mexicana.'"

In spite of the dubious character of his alleged medical education, Senese obtained appointment to an internship at the hospital mentioned. Completing the year of internship training in July, 1950, he again applied for admission to the Illinois license examinations. Again his admission was refused. He was advised that he could not be admitted to examination so long as a charge was pending against him in another state, and that the Universidad Libre Mexicana was not an accredited institution. Although barred from licensure, Senese continued to pose as a physician. On completion of his internship he secured a temporary job as an assistant surgeon at an Indiana steel plant. During the next three years he shifted his scene of operations to various hospitals in other states, including Florida and Ohio, while continuing his attempts to gain admissions to the Illinois and Florida examinations.

Armed with a genuine intern certificate and the credentials from the Mexican "universidad," Senese filed a mandamus petition against the Illinois medical board. Finally his persistence paid off. A judge of the Superior Court of Cook County signed an order that compelled the board to admit Senese to the examinations. He has taken the examination five times and, as could be expected, failed each time. Despite his license difficulties, however, Senese kept his hand in medicine. He secured an appointment in 1954 as a resident in anesthesiology in another of Chicago's better-known hospitals. He also found part-time work in other hospitals in the area. The "resident in anesthesiology" was so employed from January to September, 1954, although the hospital was notified by the Bureau of his imposture in April of that year.

In August, 1954, Senese applied for a position with a Honolulu hospital, but not as a resident—he aspired to be the head of the department of anesthesiology. In his application he claimed graduation from "the University of Mexico, located in Mexico City." He also claimed to have had "a six month post-graduate course in radiology at the University of Illinois." The head of the Department of Radiology has denied such alleged accomplishment, stating that Senese "never did do any work in this department, and I doubt that he spent more than a total of one week in the department. I turned no grade in to the Graduate College because his record was incomplete, and I had in fact banished him from the department as undesirable." Senese actually obtained letters of recommendation from generous, if undiscerning, physicians and supplemented these with one of his own creation. Using hospital stationery and the signature of the retired chairman of the department of anesthesiology, he highly recommended himself while falsifying actual dates of his service at the hospital. Another of the letters he used in applying for a position as a doctor of medicine contained this rather significant statement: "I have always admired the fact that he educated himself." While self-education may generally be regarded as an admirable accomplishment, it is hardly commendable in the field of undergraduate medical training.

The appointment as head of the department of anesthesiology came through, and the erstwhile resident traveled to Honolulu, expenses paid, in a manner befitting his new status. The appointment may have gotten Senese to Hawaii, but it did not keep him there long. According to the Better Business Bureau of Honolulu, he was discharged for incompetency approximately six weeks after his appointment. Following that, he wrote to various hospitals and physicians, seeking employment as a physician and surgeon or anesthesiologist. He apparently raised doubts as to his medical qualifications in the mind of the doctor charged with care of employees of a canning company on the Island of Molokai, who contacted the Chicago headquarters of the firm. The medical director called the Bureau of Investigation and was given the essentials of the Bureau's file. A copy of that letter was sent to the Hawaiian Territorial Medical Examiners.

The Better Business Bureau located Mr. Senese on another island, substituting temporarily for physicians who had left to attend a medical meeting in the United States. An investigator, posing as a patient, was given a diagnosis and some medication, for which she paid a fee. This information was turned over to the prosecutor's office and, as a result, Senese's medical career in Hawaii came to the end mentioned earlier. Just how many other impostors are serving as residents in large institutions in this country is not known. It would seem, however, that the checking of medical credentials, particularly of those whose degrees come from obscure institutions, should be given serious consideration by hospital administrators.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Headaches Associated with Gastrointestinal Disturbances. Z. R. Morgan. Am. J. Gastroenterol. 23:427-434 (May) 1955 [New York].

Many conditions associated with headache should be considered by the gastroenterologist. The most frequent gastrointestinal symptoms accompanying headache are abdominal distress, pain, nausea, vomiting, anorexia, epigastric fulness, pyrosis, constipation, and diarrhea. There are various types of headache, and the therapy for them differs. Relief may be obtained by proper treatment. The chief causes of headache are familial, nervous, toxic, allergic, reflex, and traumatic. Headaches often have their origin in certain organs or systems, namely cardiovascular, gastrointestinal, cerebral, blood dyscrasias, anemia, otic and ocular disorders, gynecologic, and renal disturbances. Besides having their origin in one of these systems, headaches may also originate from hormonal disturbances, sugar imbalance, fatigue, and worry. They are often associated with systemic diseases. The causes of headache may be multiple including alkalosis associated with high intestinal obstructions; duodenal stasis; splanchnoptosis; gastrointestinal dysfunction resulting from vagal irritation; typhoid fever; toxemias without fever associated with diseases of the liver and kidney; exposure to extrinsic poisons such as carbon monoxide, arsenic, or lead; low blood sugar level; cecal stasis caused by atony, adhesions, or congenital bands; fatigue; and constant or intermittent emotional stimulation or conflict. The causes of headache observed by the gastroenterologist thus require an understanding of the phenomena responsible for them.

Methyl Testosterone for Migraine in Women: Report of 60 Cases. R. C. Moehlig. J. Michigan M. Soc. 54:577-579 (May) 1955 [St. Paul].

Methyl testosterone was used in 60 women with migraine. Eleven derived no benefit from this treatment, but 49 were improved. Not only were their attacks of migraine relieved, but their sense of well-being and mental attitude improved. In an earlier group of patients the author gave 20 mg. of methyl testosterone daily for four weeks followed by daily doses of 10 mg. for an additional two weeks, but now he gives 10 mg. daily for four weeks, then 10 mg. every other day for an additional eight weeks, and from then on the medication is given every third day for an additional eight weeks. The smaller dose was found to be just as efficacious as the 20 mg. dose and less likely to give undesirable effects. Some patients continued taking the medication every third day for three years, but the majority took it for only three months. When relapses occurred they usually came on three months after the discontinuance of therapy, but the recurrent attacks of migraine were generally less severe than were the original attacks. Treatment with methyl testosterone must be carefully supervised since undesirable secondary effects are likely to result in women. Hirsutism resulted in 12 of the 60 women and necessitated interruption of treatment, and when treatment was resumed later, the doses were reduced, or spacing between doses was prolonged. Acne appeared in 27, deepening of voice in 13, menstrual disturbances in 29, increase in weight in 40, nervousness in 18, and increase in libido in 28 of the women. Furthermore, prolonged administration of testosterone may produce thyrotoxic symptoms in women with goiter and lessening of the carbohydrate tolerance in diabetic women. Nevertheless, the author believes that methyl testosterone deserves a trial in women with migraine headaches.

Clinical and Physiological Studies on the Use of Metacortandracin in Respiratory Disease: I. Bronchial Asthma. A. L. Barach, H. A. Bickerman and G. J. Beck. Dis. Chest 27:515-527 (May) 1955 [Chicago].

Prednisone (Metacortin) was given in four divided doses daily, generally at mealtime and between 11 and 12 p. m., to 30 patients with bronchial asthma. In patients with intractable bronchospasm a dosage of 60 to 80 mg. a day was used for one or two days; 40 to 60 mg. per day for three or four days; and 10 to 30 mg. daily thereafter, depending on the response of the patient. In patients in whom a maintenance dosage of 60 to 100 mg. of hydrocortisone had previously been used, the dosage of prednisone varied between 20 to 40 mg. a day. The response to treatment with either cortisone, hydrocortisone, or corticotropin was known in 18 of the 30 patients in this series. The short-term treatment with prednisone caused disappearance or relief of bronchospasm and asthmatic dyspnea in 29 of the 30 patients and the ability to eat a regular diet with added salt and without the use of supplementary feeding of potassium in patients without heart disease, in contrast to the need for a salt-poor diet and potassium administration with the administration of cortisone, hydrocortisone, and corticotropin. In 5 patients previously on maintenance therapy with hydrocortisone, the substitution of prednisone for hydrocortisone resulted in an average weight loss of 6 lb. in one week. In six patients mooning of the face became much less prominent. The subjective effect of eating a regular diet in the patients without cardiac failure was a happy one. The side-effects were slight, resembling, but to a lesser extent, those seen with cortisone treatment, i. e., mental stimulation, abdominal discomfort, occasional headache, and transient dizziness. Respiratory function tests confirmed the clinical impression of decrease or disappearance of bronchospasm. The authors believe that this new steroid hormone is of great value in the treatment of intractable bronchial asthma. Furthermore, prednisone, in contrast to cortisone, is safe in patients with persistent asthmatic dyspnea and with associated cardiac insufficiency. Further studies will be necessary to ascertain to what extent prednisone will lower resistance to infection. The long-term effects of prednisone are not known, but all of the side-effects of cortisone, except for salt and water retention, have already been observed.

Symptomatology and Therapy of Thrush-Mycosis of Lung. W. Straube, W. Hahn and H. Seeliger. Deutsche med. Wchnschr. 80:753-755 (May 13) 1955 (In German) [Stuttgart, Germany].

The occurrence of secondary mycosis of the lung caused by Candida albicans is reported in a 20-year-old man who had been treated at home by his family physician for bilateral severe pneumonia with large doses of Omnacillin (a suspension of procaine penicillin G in 1 cc. of concentrated Omnadin [a mixture of reactive protein bodies from various nonpathogenic fungi with biliary lipids and animal fats]), Supracillin (a penicillin-streptomycin preparation), chlortetracycline, oxytetracycline, and chloramphenicol. The roentgenologic picture was that of caseating pneumonia that did not respond to the antibiotic treatment. There was complete failure of the immunologic defense powers. When admitted to the hospital, the patient had severe dyspnea and circulatory collapse refractory to treatment, mycotic stomatitis, an extensive maculopapular eruption on the trunk and the ex-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

mities, diarrhea, and hemoptysis. The liver was tender and larged. Mycobacterium tuberculosis, mycelia, and C. albicans re observed in the sputum. C. albicans also was found in the es. The patient was given streptomycin, isoniazid, and Solupronal (a 20% aqueous solution of a mixture of equal parts sulfamerazine and of the 4-amino methyl benzene sulfonade salt of sulfathio-urea). After 85 days of treatment the pant improved and was discharged from the hospital, but mas tuberculous infiltration was still revealed by the roentgenom. Two and a half months after his discharge the roentlogram showed restoration of conditions to almost normal h slight pleural adhesions on the left side. The occurrence of umonia caused by C. albicans in the course of treatment with e doses of antibiotics must always be considered a serious nplication, since as a rule only patients with lowered resiste are affected. The destruction of the physiological bacterial a results in a change of the causative agents in favor of the mally nonpathogenic yeasts and fungi and in severe disturbes of the vitamin metabolism. Mycosis of the lung caused by albicans must be considered in the differential diagnosis of te pulmonary disease. The reported case suggests that the ications for antibiotic therapy should be carefully observed. erminations of resistance are indispensable, and signs of unirable side-effects must be recognized promptly if treatment is longed. Because of the great risk associated with the continum of antibiotic treatment in patients with lowered resistance l mycosis of the lung, Solu-Supronal in large doses should be n a therapeutic trial.

alosis and Hypopotassemia in Anorexia Mentalis ("Starva-Alkalosis"). P. H. Rossier, D. Staehelin, A. Bühlman and Labhart. Schweiz. med. Wchnschr. 85:465-468 (May 14) 1955 German) [Basel, Switzerland].

eterminations of serum electrolytes and carbon dioxide conts of plasma or serum and measurements of blood pH were ried out in 10 women between the ages of 20 and 28 years n anorexia nervosa. In the patients with severe anorexia vosa, a fixed alkalosis was observed that was completely npensated by hypoventilation with retention of carbon diox in one patient, and only incompletely compensated in aner. In the patients with mild anorexia nervosa, the pH of arterial blood did not differ much from that in normal pers. Of the seven patients with severe anorexia nervosa, six had opotassemia. The potassium level in the serum of one of these ients was extremely low (7.6 mg. per 100 cc.) and was ociated with changes of the electrocardiogram typical of hypoassemia. In patients with definitely low serum potassium els, the potassium concentration in the erythrocytes also below normal, and the excretion of potassium in the urine minimal. The concentration of sodium in the serum of all patients was normal or slightly increased. In patients with ere alkalosis the chloride values in the serum were low. Alkais and hypopotassemia are the results of prolonged underrishment induced by anorexia nervosa. These findings are contrast to those of acidosis, which may be observed in ting of short duration. A negative potassium balance of longed duration apparently is the cause of the hypopotasnia and of the reduction of the intracellular potassium. In onic starvation the kidneys are not able to maintain potasm balance in the serum. The alkalosis is of a metabolic type, l an exchange between sodium ions and hydrogen ions in tubules may also be a pathogenetic factor. The recognition alkalosis associated with hypopotassemia in patients with rexia nervosa is not only of theoretical interest, but also importance with regard to differential diagnosis from dises of the pituitary body (Simmond's disease) and from dises of the adrenals. Although anorexia nervosa is primarily psychotherapeutic problem, severe cachexia and dehydration y require infusion therapy. Potassium chloride should be ded to the infusion in order to obtain an isotonic concentran of from 15 to 20 mg. per 100 cc. The administration of concentrated potassium solution is indicated when the serum tassium level is below 10 mg. per 100 cc.

Thyroid Function in Disorders of the Hepatic Parenchyma. B. R. Scazziga, L. L. Barbieri and T. Béraud. Schweiz. med. Wschnschr. 85:471-477 (May 14) 1955 (In French) [Basel, Switzerland].

Thyroid function studies, including determination of the basal metabolic rate, the serum protein-bound iodine, the uptake of radioactive iodine (I^{131}) by the thyroid after the administration of 200 μc of I^{131} on a fasting stomach, and the radioiodine conversion ratio, were carried out in 33 patients with disorders of the hepatic parenchyma. Of these, 19 had epidemic hepatitis, 10 had alcoholic cirrhosis of the liver, and 4 had primary or metastatic carcinoma of the liver. In the patients with epidemic hepatitis, the serum protein-bound iodine levels were high compared to normal values but the uptake of radioactive iodine by the thyroid and the radioiodine conversion ratio were low as compared with those in healthy persons. The patients with cirrhosis did not show significant changes in the serum protein-bound iodine levels, the uptake of radioactive iodine by the thyroid, and the radioiodine conversion ratio as compared with results obtained in normal persons. Two of the four patients with carcinoma of the liver showed higher serum protein-bound iodine levels than those observed in normal persons, but the uptake of radioactive iodine by the thyroid was low and the radioiodine conversion ratio was definitely below normal. These two patients had extensive metastases and their general condition was poor. The two other patients with carcinoma of the liver did not show a significant disturbance of the thyroid function. These observations suggest that impairment of the hepatic parenchyma may entail a disturbance of the catabolism of thyroxine manifested by an increase in the ratio of circulating hormone and accompanied by secondary thyroid hypofunction. Hyperthyroxinemia on one hand could be the expression of an insufficient destruction of the hormone at the level of the impaired hepatic cell, and on the other hand it could be the sequela of a disturbance of biliary elimination of thyroxine. The increase in the ratio of circulating hormone induces checking by the pituitary, which explains the signs of thyroid hypofunction revealed by the radioiodine tests. The absence of significant changes of thyroid functions in the patients with cirrhosis suggest that the impairment of the liver was less generalized than in the patients with hepatitis and that the functionally unimpaired portion of the parenchyma was sufficient to insure a normal catabolism of thyroxine. The same explanation seems to be warranted in the two patients with carcinoma of the liver and normal thyroid function. These observations in addition made evident the difficulties of interpreting thyroid function tests when peripheral extrathyroid factors are exerting their influence on thyroid function.

Alimentary Disturbances of Circulation as Cause of So-Called Dumping Syndrome. W. Schrade and R. Heinecker. Schweiz. med. Wchnschr. 85:481-488 (May 14) 1955 (In German) [Basel, Switzerland].

The clinical symptoms of which the so-called dumping syndrome consists indicate that disturbances of circulation may play a part in this sequela of gastrectomy. Besides signs of disturbed blood perfusion of the periphery, and particularly of the brain, alterations of blood pressure may be observed after the ingestion of food in patients who undergo gastrectomy. These alterations consist partly of rise and partly of lowering of blood pressure occasionally to collapse levels, while the frequency of the pulse increases regularly. The authors made sphygmographic studies of circulation immediately after oral administration of 100 gm. of dextrose in 11 patients who had been subjected to gastrectomy and after intrajejunal administration of dextrose in 3 normal persons. The amount of blood circulated through the heart was greatly changed immediately after the administration of dextrose in the patients operated on. The cardiac output and the minute volume of the heart either increased as they do in persons not operated on, the increase occurring earlier and more extensively than in healthy persons; or the cardiac output and the minute volume dropped in an unphysiological way as a result of the alimentary stimulus. The increase in the minute volume is related to an active hyperemia of the region of the splanchnic nerve and the decrease of the minute volume manifests a passive "bogging down" of the blood in the digestive organs. In patients standing erect, these alimentary reactions combine with the orthostatically conditioned displacement of blood and thus cause the risk of an alimentary precollapse or collapse. Alleviation of the dumping syndrome in the recumbent position is not the consequence of delayed emptying of the stomach but is conditioned by the hemodynamics. The alimentary disturbances of circulation are the real cause of the general complaints of patients with dumping syndrome. The abnormal blood perfusion of the region of the splanchnic nerve after ingestion of food causes impairment of the blood supply to the rest of the body, particularly to the brain. The marked hyperemia of the digestive organs and thus the occurrence of the dumping syndrome can to a great extent be prevented mechanically by the use of a body bandage.

SURGERY

The Management of Instrumental Perforation of the Esophagus. J. T. Howard. Am. J. Gastroenterol. **23**:399-410 (May) 1955 [New York].

Perforation of the esophagus resulting from examination with the esophagoscope and a rubber-tipped obturator to facilitate the passage of the stiff esophagoscope or from simple stretching with the pneumatic dilator occurred in five patients between the ages of 48 and 70 years with dysphagia. Esophageal instruments should be passed into the esophagus gently and without undue apprehension. Because the hypopharynx of a woman weighing 95 lb. (43 kg.) or a frail 70-year-old man is not as resistant to trauma as that of a younger man of average nutrition, it is essential to pay attention to any postinstrumentational complaints of the patients and to treat these promptly. The patient should be hospitalized, and if the perforation is relatively high in the esophagus treatment should consist of placing the patient in the Trendelenburg position, total intravenous or tube feeding with suction on the lower esophagus, and antibiotics. When conservative measures are unavailable or if the injury to the esophagus seems to be too extensive for conservative treatment, suturing of the perforation should be performed.

Mechanical Intestinal Obstructions: A Study of 1,252 Cases. G. A. Smith, J. F. Perry Jr. and E. G. Yonehiro. Surg., Gynec. & Obst. **100**:651-660 (June) 1955 [Chicago].

In 1,252 episodes of obstruction in 1,079 patients the most common causes were postoperative adhesions, primary and recurrent carcinoma of the intestine, and external hernia. Jejunal and ileal obstruction was most commonly due to adhesions and external hernia, while primary carcinoma was by far the most frequent cause of colic obstruction. Patients were from all age groups, but the majority were middle aged or older (40% were over 60 years old). There were 157 deaths from all causes, a patient mortality rate of 14.5%, and a case mortality rate of 12.5%. If only the patients who died from intestinal obstruction are considered after excluding 68 patients whose deaths were due to unrelated causes or who were moribund on admission, the patient mortality rate and case mortality rate are reduced to 9 and 7.5% respectively. In treated patients, the prognosis was less favorable in those with jejunal and ileal obstruction than in those with colic obstruction, apparently because of the more frequent occurrence of gangrene in those with obstructions of the small intestine. The major factors that adversely influenced survival were gangrene, intestinal perforation, severe intestinal distention, and extreme youth or extreme age of the patient. A 12-hour trial of intestinal suction is warranted in small-intestine obstructions without signs of strangulation. When active peristalsis is present the chances for decompression are good, but the atonic intestine of late mechanical obstructions usually thwarts nonoperative attempts at decompression. Patients treated by suction are reevaluated at the end of 12 hours by roentgen examination of the abdomen. If there has been a significant reduction in distention and if clinical improvement is progressive, suction is continued, but signs or symptoms suggesting strangulation, obstruction, or failure to relieve distention are indications for operation. Rapid intubation of the small intestine using the flexible stylet with controllable tip offers the surgeon some control of the time required for passage of the tube as well as placement of the catheter into the jejunum at the time of initial intubation. Distention is managed at operation by passage of the tube through the intestine with the stylet or by aseptic decompressive enterotomy. The application of the stylet as a guide for rapid small-intestine intubation at the time of operation has now been used successfully in over 50 patients. Enterostomy has a limited place for decompression in patients nearing the moribund state and in patients with early postoperativ distention proximal to a colic anastomosis. The latter group i best managed by an emergency cecostomy or appendicostomy Strangulated obstructions require immediate operations with th intent of primary resection of nonviable intestine. Although oc casionally colic distention can be relieved by suction or oth nonoperative methods of decompression, the treatment of col obstruction is primarily surgical. Giving antibiotics preoper tively and for several days postoperatively may reduce po operative peritonitis.

Surgical Significance of Gastrointestinal Bleeding. C. Mathews Jr. and B. Sugar. Am. J. Surg. **89**:1177-1181 (June) 1955 [N York].

The mortality from massive gastrointestinal hemorrhag still alarmingly high. Among 215 cases studied at the San F cisco Hospital during the years 1947-1952, the over-all mo ity rate was 33%. The mortality rate from proved gastri duodenal ulcer was 12.3%. Fatal gastrointestinal bleeding al invariably has its source above the ligament of Treitz and ca controlled adequately in carefully selected patients by emerg operation during the acute stage of bleeding. An emerg operation is indicated in a selected group of patients who d respond to conservative measures and in those who have r rent bleeding while under observation. It should be bor mind that the death rate from hemorrhage increases sh after the age of 45. There seems to be a definite correlatio tween bleeding and the presence of arteriosclerosis. W patient with suspected acute gastrointestinal bleeding is adn to the hospital, blood studies are made at once, including to rule out hemorrhagic diathesis and primary blood dis A slow drip blood transfusion is started. Failure to respo transfusion is the major indication for early operation. and blood pressure are recorded every 15 minutes. Evide severe or continuing blood loss is best obtained from the ence of pallor, restlessness, and sweating. Constant obse of the patient is essential. If stabilization occurs, as it does after two or three 500 cc. whole blood transfusion if bleeding does not recur, conservative medical mana may be continued. Massive gastrointestinal hemorrhage tients over 45 is a definite indication for later gastric resec

Postmastectomy Lymphedema: A Clinical Investigation Causes and Prevention. R. P. Villasor and E. F. Lewison Gynec. & Obst. **100**:743-752 (June) 1955 [Chicago].

In order to evaluate the numerous factors that may be to the development of lymphedema of the arm after mastectomy and to devise measures to prevent this u complication, studies were made on 51 patients with ar ing who had undergone radical mastectomy; 28 wom were free from this complaint after mastectomy served trols. All patients were selected and did not constitute a utive series. Patients with local metastases were include study, but those with remote osseous or pulmonary m were excluded. The cause of postmastectomy lymphe difficult to determine and may vary from patient to pat single common denominator could be found that wo sistently account for the development of this distressin tion. In 57% of the first series of patients, postmas lymphedema developed shortly after operation without minant inciting factor. Infection accounted for the con 16% and impaired venous return for another 6%. Lym lso followed venipuncture, over-exertion of the arm, and supra- avicular metastassis. In 16% of the patients, the onset of lym- hedema was delayed and the precipitating factor was unknown. he following factors, alone or in combination, may have some :aring in the development of postmastectomy lymphedema:) infection, (2) axillary metastases, (3) postoperative radio- erapy, (4) operative scars that are tight and encroach on the m and axilla, (5) injury or thrombosis of the axillary vein,) excision of the clavicular head of the pectoralis major muscle,) delayed mobilization of the arm, (8) injections into the homo- teral arm, and (9) local or regional recurrences. Since treat- ent of the swelling is seldom satisfactory the authors enumer- e as preventive measures those designed to avoid the afore- entioned causal factors.

ıe Walking Venous Pressure Test in Relation to Occlusive rterial Disease in the Lower Extremities. J. H. Schneewind, N. Mansour and W. J. Grove. Surg., Gynec. & Obst. 100:697- 12 (June) 1955 [Chicago].

The measurement of venous pressures in the legs during exer- se is a much more valuable index of the efficiency of venous ainage than is the measurement of venous pressures during st. In a series of 16 patients with arterial insufficiency of the wer extremities, none of whom had serious venous derange- ent, the walking venous pressure tests caused a fall in venous essures due to the pumping action of the muscles. The authors ırned to direct their attention to the type of venous pressure sponse obtained immediately after exercise. These tests were ıne before and after lumbar sympathectomy. Patients with oderate arterial insufficiency showed essentially normal venous essure return immediately after exercise and those with more vere arterial obstruction showed moderate to marked delay venous pressure return immediately after exercise. The find- g of an impaired postexercise venous pressure response seemed correlate best with the degree of arterial occlusion as shown arteriography. In every patient in whom an absent or delayed ıstexercise venous pressure pattern was noted prior to sympa- ectomy, a much improved or normal postexercise venous essure response was observed after operation.

ısttraumatic Dystrophy. J. Bonnet. Arch. chir. neerl. 7:37-64 o. 1) 1955 (In English) [Arnhem, Netherlands].

Bonnet believes that the syndrome of post-traumatic dys- ophy includes several clinical pictures hitherto regarded as parate post-traumatic disturbances, e. g., fracture, edema, hard aumatic edema of the dorsum of the hand, erythromelalgia, nyotrophy, and painful osteoporosis. Only causalgia is often ll regarded as a separate clinical entity. Some authors still ınnect Sudeck's name with these post-traumatic forms of dys- ophy. A clinical analysis of about 100 cases of post-traumatic rstrophy led the author to differentiate four stages of post- aumatic dystrophy, which differ from most of the classifications und in the literature. The first stage is characterized by vaso- latation; its symptoms are hypertrichosis and finely spotted calcification of bone in addition to a warm, dry, edematous in. The second stage is characterized by vascular instability d by fluctuations in the clinical manifestations. During the ird stage vasoconstriction is virtually constant and results in e atrophy of all tissues. The fourth or residual stage is aracterized by normal circulation; there is no pain; the tem- rature and the appearance of the skin are normal; there is rsistent atrophy of muscles and bone; and the contractures e irreversible. The therapeutic results are best when treatment instituted at an early stage. It is therefore important that a ndency to dystrophy in cases of injury be recognized early, d that its further progression be prevented by avoidance of adequate or insufficiently prolonged immobilization, of opera- ons, of refracturing, and of massage. Satisfactory results were a rule obtained during the first stage by immobilizing the tremity with the aid of a zinc sulfite bandage, an arm sling, r plaster-of-Paris. Passive movements and massage are in- dvisable, as they may lead to exacerbation of the dystrophy. ctive movements are permitted in mild cases. Procaine injected cally may produce definite improvement in patients with ains at definite points, such as at the fractured styloid process in patients with Colles' fracture. Excision of a thrombotic vein or of cicatricial tissue may likewise be helpful. In the absence of marked trigger points, or when local procaine injections do not give satisfactory results, sympathetic block may produce improvement. The addition of epinephrine to the solution used in sympathetic block causes local vasoconstriction. It prolongs and enhances the effect of procaine by less rapid absorption and does not antagonize this effect. On the basis of these theoretical considerations, epinephrine was added to the 1% procaine solution used in sympathetic block. The addition of epinephrine in alternate cases showed that it improved the effects, and since then the author has been adding it to all solutions. The author suggests that post-traumatic dystrophy is the result of changes in the sensitivity of the blood vessels (and perhaps of the sweat glands) to central stimuli under the influence of local and regional reflexes caused by the trauma. It seems probable, moreover, that these reflexes originate particularly from the injured capsules and ligaments of the smaller joints.

NEUROLOGY & PSYCHIATRY

Fatal Forms of Mumps Meningoencephalitis. Mazaré and Guffon. J. méd. Lyon 36:343-349 (May 5) 1955 (In French) [Lyon, France].

A search of the world literature, after the development of fatal meningoencephalitis in a 19-year-old man following mumps, showed only 29 earlier instances of this rare complication. The onset of the patient's illness was mild, but on the seventh day his temperature rose without warning to 101.3 F, subsequently remaining between 102.2 and 104 F. General convulsive crises developed, and on the 10th day the patient was admitted to the hospital in coma vigil without stertor. Examination showed a bilateral parotid swelling in regression, unmistakable signs of meningeal involvement, and orchitis on the left side. The treatment the patient had been receiving—streptomycin, penicillin, and chloramphenicol—was continued with the addition of cardiac stimulants, adrenal cortical extracts, a sedative, and ice on the head. His condition grew steadily worse, however, and three days later he died in spite of an attempt at hibernation therapy. Meningoencephalitis complicating mumps usually follows the parotid involvement, but in five patients it appeared first. The parotitis, which is bilateral, is always intense and is often associated with submaxillitis in the fatal cases. Only 10 of the recorded deaths occurred in children under 11, as compared with 16 in young adults aged 19 to 25. A few reports failed to state the patient's sex, but of the 22 patients for whom this information is given 19 were males. A period of improvement and reduction of fever usually precedes the sudden rise in temperature that marks the onset of the meningoencephalitis. Disturbances of consciousness dominate the clinical picture and convulsions, which seldom occur in the benign forms, are not infrequent, especially in children. Three types of the disease—paralytic, psychic, and convulsive—can be distinguished according to the symptoms predominating in each case. The course is usually rapid: the patient soon becomes comatose and death follows, often within 4 to 15 days. There is no specific treatment, but the excellent results obtained with hibernation in severe forms of acute infectious meningoencephalitis due to causes other than the mumps virus suggest that it should be given a further trial.

Reserpine in Treatment of Chronic Psychotics: Preliminary Observations. E. S. Foote. Brit. M. J. 1:1192-1193 (May 14) 1955 [London, England].

Thirty-two chronically mentally disturbed men were treated with reserpine for periods of up to five months. In most, great improvement was noted in their habits and personal appearance and in their ability to occupy themselves. Impulsiveness and incontinence disappeared. A marked quieting effect was noted. Even those showing definite signs of dementia were superficially improved. Side-effects were slight and occurred in only a few. Most patients who are going to respond show signs of this within a week or two, but some received the drug for three months before definite improvement was noted. It is therefore suggested that unless the patient's condition deteriorates the method should be given at least a three-month trial. The promising results obtained in this small series of mentally disturbed patients suggest that an extensive trial of reserpine in patients whose psychoses are of recent onset should be conducted. Full use should be made of occupational and recreational therapy to provide the stimulus for activities that the drug appears to permit.

Mental Changes Observed in 152 Psychotic and Non-Psychotic Patients During INH Medication. R. Rosenfeld. Dis. Chest 27:558-562 (May) 1955 [Chicago].

Isoniazid was given either alone or combined with streptomycin, p-aminosalicylic acid, pneumoperitoneum, pneumothorax, phrenic nerve crush, or a thoracic operation in 152 patients with tuberculosis, of whom 149 had been mentally ill, mentally deficient, alcoholic, or psychopathic prior to treatment with isoniazid. Two had been mentally normal before isoniazid medication, and one was mentally normal during the last eight years prior to isoniazid treatment but had been hospitalized for a manic-depressive psychosis twice (8 and 10 years earlier). Those three had been committed to the hospital for an acute psychosis that developed during isoniazid treatment, following extensive chest surgery in another tuberculosis hospital. Isoniazid was given in doses ranging from 200 mg. to 500 mg. daily for two weeks to one year. Various stages of pulmonary tuberculosis were present in 148 patients. Two had tuberculous lymphomas and two bone tuberculosis. The mental diagnoses were: schizophrenia in 79, manic-depressive psychosis in 6, senility in 4, alcoholism in 8, general paresis in 3, mental deficiency in 12, cerebral arteriosclerosis in 9, involutional psychosis in 2, Huntington's chorea in one, and sociopathic personality in 25. The effects of isoniazid on the tuberculosis did not differ appreciably from the results obtained with this drug in other tuberculosis hospitals. Isoniazid, besides being a potent antituberculous drug, has a stimulating effect on the central nervous system. It can cause epileptic seizures in epileptics, and its use is therefore inadvisable in such persons. Besides this side-effect isoniazid seems also to be able to influence the behavior and mental condition of psychotic and nonpsychotic persons. The author observed striking mental improvement in only one patient, whereas 24 others showed mental improvement to a slighter degree. Patients who had been uncooperative became cooperative. Hostile patients became friendly and sociable. Untidy ones became clean. Aggressive patients, who had formerly been in restraint for long periods, became quiet and could be taken out of restraint. Stuporous ones became more alert. There was apparently no connection between improvement of the tuberculosis and improvement or changes in the mental status.

Rehabilitation of the Hemiplegic Patient: A Clinical Evaluation. F. J. Mahoney, D. W. Barthel and J. P. Callahan. South. M. J. 48:472-480 (May) 1955 [Birmingham, Ala.].

Treatment of the hemiplegic patient should not be limited to medical care in the case of cerebral vascular accidents or surgical care in cases of brain injuries or brain tumors but should progress to rehabilitation. Survival of a hemiplegic patient as a bed-ridden invalid benefits neither the patient nor his family. The aim of the rehabilitation treatment should be: (1) independent "self-care" and ambulation; (2) recovery of all possible muscle power and range of motion; and (3) training in coordination, balance, and endurance sufficient to permit as much independent "self-care" as possible. The goal should be set individually according to what each patient can attain with whatever amount of disability he has as a result of his cerebral vascular accident or brain injury. Most hemiplegic patients, even when there is little or no return of muscle function in either the upper or lower extremity of the involved side, can be taught the following "self-care" activities: ambulation around the house, getting in and out of bed and changing positions in bed, feeding and dressing themselves, getting in and out of chairs and a car, going to the toilet and attending to personal toilet, and going up and down stairs with a hand rail. With slight assistance, these patients can usually get in and out of a bathtub and with no assistance can take a shower sitting on a stool. When there is cardiac decompensation or other complications that will vent ambulation, the patient should be taught to be as pendent as possible with a wheelchair, thus relieving the fa of a great burden. The patient must be motivated to wo becoming independent, and the family and/or ward pers must discourage dependence. These goals are more accomplished when rehabilitation begins early and the pa is not permitted to enjoy being an invalid.

GYNECOLOGY & OBSTETRICS

A Simple Method of Treating Vulvovaginal (Bartholin) and Abscess. E. M. Wilder. South. M. J. 48:460-464 (1955 [Birmingham, Ala.].

Infections of the vulva may occlude the opening of the of the vulvovaginal gland of Bartholin, and an abscess form. After the infection subsides the gland continues to s and a thin-walled cyst results. A Bartholin cyst rarely symptoms; but the periodically recurring abscess causes ex pain and discomfort. The author shows that the treat recommended in textbooks are too radical and haza Furthermore, the radical excision of the gland results i of important lubrication. These women complain of dyspa and dryness of the vulva. Many have a deformed and s vulva with its deplorable consequences. The procedure des by the author and those suggested by Davies and Jacobso at the reestablishment of the ostium of the duct to supply age and permit the gland to function again. The cyst wa comes the new duct communicating with the still functi gland. In the author's technique, which is an office proc an incision about 2 cm. long is made over the cyst w abscess close to the original opening of the duct. Four silk sutures are placed from inside the cyst or abscess wall and including the skin of the vestibule and labia. An form drain is inserted in the abscess or cyst cavity. The is removed in about one week. The operation can be don mediately post partum, provided the infection is not an process. After three weeks the silk sutures are removed new patent ostium is evident. From 1948 to 1950 the a treated 18 patients, using Davies' technique, the final being excellent in all 18, of whom five had abscesses an remainder cysts. Between 1950 and the end of 1954 he tr 48 patients with acute bartholinitis and 32 with cyst by his modified method. The results were excellent in all pat although one with bilateral cyst tormation required operations on each side.

Endometrial Cancer with Positive Biopsy Not Confirme Operative Specimen. R. A. Defilippo. Rev. Asoc. méd. ar 69:5-8 (Jan.-Feb.) 1955 (In Spanish) [Buenos Aires, Argen

Conflicting results between a positive biopsy of endom cancer and negative results of the histopathological examin of the removed uterus have been explained as proof of of cancer by biopsy. A positive biopsy of endometrial ca calls for hysterectomy. The cure effected by biopsy is ve by histopathological examination of the removed uterus, w as the possibility of cure should not be relied on as an expec treatment. The practice of sending portions of the same bi to more than one pathologist may result in contradictory ings in the various sections. Positive results in a portion of biopsy prevail over negative results in the other port Hysterectomy confirms the diagnosis of cancer. The author ports three cases of endometrial cancer with such conflict results. The whole endometrium in the removed uterus observed. A small focus of granulation tissue containing plastic cells that were identifiable with those of the biopsy found in two cases. It proved to be the zone of implantat of peduncular adenocarcinomatous and carcinosarcomat polyps respectively. No cancerous lesion was found in the en metrium of the third patient. The author concludes that biopsy effects a cure of endometrial cancer by section peduncular neoplasms by the pedicle or by extirpating the wh neoplastic lesion of early noninfiltrating cancer. The histopat logical examination of the removed uterus should include t e endometrium to prevent overlooking of the basis of im- ation of polypous carcinomas or residual zones of malig- after extirpation of complete lesions of early noninfil- g neoplasms. In evaluating the cure of endometrial cancer opsy, the possibilities of loss and accidental substitution ecimens, diagnostic errors, and the removal of a malignant of transitional endometrial glandular hyperplasia should minated.

igation on the Function of the Adrenal Cortex Before ery and in the Early Puerperal Period. T. Ozbay. Zen- Gynäk. **77:**372-384 (No. 10) 1955 (In German) [Leipzig, any].

five healthy pregnant women, who had a normal delivery, cretion of adrenal cortical hormones was determined in st weeks before delivery as well as during the early puer- n. Daily urinary corticoid and 17-ketosteroid determina- were made. During the last weeks of pregnancy the oid content of the urine was about twice as high as in egnant women who had normal menstrual cycles, but im- tely after delivery the corticoid content of the urine de- d rapidly and within a short time was only 20% above f nonpregnant women. The 17-ketosteroid content of the was about 50% above normal before delivery, but during uerperium the urinary concentration of 17-ketosteroids d no increase whatsoever.

LARYNGOLOGY

gillosis of the Ear: A Report of 29 Cases. E. A. Stuart. l. M. A. J. **72:**334-337 (March 1) 1955 [Toronto, Canada].

e fact that 29 patients with otomycosis due to various s of Aspergillus were diagnosed and treated at the Royal ria Hospital in Montreal, Canada, indicates that otomy- aspergillina is more common in this region than reports is disease would suggest. Eleven of the 29 patients in this (group 1) had no history of previous ear infection, except e instance where a simple mastoidectomy had been per- d many years earlier. Five cases occurred in patients with ic eczema of the ears (group 2). Seven patients already chronic suppurative otitis media (group 3). Three cases red after the use of antibiotic powders in cavities result- om radical mastoidectomy (group 4), and three others fol- l the general use of antibiotics (group 5). Large mycelial s were removed from the auditory canal of most of the nts. Microscopic and cultural examinations of the debris made in all cases, but in 13 cases no bacteriological in- gations were made, because the diagnosis of aspergillosis o strongly suggested clinically. A light to moderate growth icrococcus (Staphylococcus) pyogenes was found in 6 of emaining 16 patients in whom bacteriological studies were . No bacteria were found in five of eight patients of group ho were bacteriologically examined, but in two of these the symptoms were severe and signs suggested otitis media. us was found in the middle ear, and the author believes that ymptoms and signs resulted from the mycotic infection. In ps 2 and 3 the unhealthy skin and moisture of eczema and nic suppuration provided a medium for the growth of the us. No further comment is made on the six cases of otic rgillosis associated with the local or general use of anti- cs. The author believes that mycological investigations of auditory canal in addition to the bacteriological examina- should be of great assistance in arriving at a proper diag- and more effective treatment in otitis externa.

oration of Hearing in Otosclerosis by Transtympanic Mobil- on of the Stapes: Preliminary Report of Fifty Cases. A. A. er. A. M. A. Arch. Otolaryng. **61:**513-534 (May) 1955 cago].

series of 50 patients with otosclerosis was treated by the stympanic method of mobilization of the stapes. The tech- e employed was that of Rosen, which was described in *A. M. A. Archives of Otolaryngology* (61:197-206 [Feb.] 1955; abstracted in THE JOURNAL **158:**235 [May 21] 1955). The patients were followed from 6 to 10 months after the transtympanic mobilization of the stapes. Forty-seven of the stapes were found to be fixed at the time of operation, and 31 were mobilized, but only 15 obtained a group A result (return of hearing to a serviceable level of 30 db. or better). Sixteen of the stapes were fractured because they were too fixed. Two stapes in patients with group A results became refixed in the fenestra ovalis after mobilization but were remobilized, with a return of hearing to the original postoperative level. Postoperative infection probably hastens the refixing of a mobile stapes. A fenestration can be successfully performed after an unsuccessful mobilization.

PATHOLOGY

Atrophic Gastritis of the Fundus in Pernicious Anemia: Biopsy Investigation. C. Debray, R. Laumonier, F. Besançon and P. Housset. Arch. mal. app. digest. **44:**28-40 (Jan.) 1955 (In French) [Paris, France].

Fifty patients with pernicious anemia were examined by gastric biopsy. The classic descriptions of the gastric lesions were confirmed by this study. No patient had a normal fundic mucosa. The lesions were spread throughout all parts of the mucosa, they were all of long standing and of an irreversible nature, and they were heterogeneous. The authors were unable to throw any light on the question of which cells secrete the intrinsic factor. Unequivocal histological criteria cannot be set up for the diagnosis of pernicious anemia from biopsy evidence, but certain signs are strongly suggestive: a greater degree of fundic atrophy than in other diseases, less cellular differentiation, and the extensiveness of the lesions. As to the question of how pernicious anemia develops, it is suggested that several conditions must be fulfilled simutaneously: the atrophic gastritis must be generalized, severe, and irreversible in order to cause significant deficiency of the intrinsic factor, and the organism's reserves of vitamin B_{12} must be totally exhausted. Although in general the lesions, though extensive, remain clinically asymptomatic for a long time, the authors found that, on careful questioning, about a third of their patients suffered from epigastric pain. When the diagnosis of pernicious anemia is easily made, gastric biopsy is not an essential test; if it is done, it is the natural complement of gastroscopy. On the other hand, in difficult cases, biopsy is indispensable.

Secondary Tumours of the Heart and Pericardium. R. B. Goudie. Brit. Heart J. **17:**183-188 (April) 1955 [London, England].

Of the 4,687 consecutive postmortem examinations performed in the Western Infirmary, Glasgow, Scotland, during the years 1940 to 1953, there were 1,270 cases of malignant disease of which 126 (10%) showed secondary tumors of the heart or pericardium. Since a special search for cardiac involvement was not made in these routine necropsies, the true incidence is likely to be higher than this. Tumors of the heart and pericardium are often clinically silent, and, even when they produce symptoms or signs, these are usually overshadowed by the effects of the primary tumor or a metastasis to another organ. In only 20 of the 127 cases in the present series was the attention of the clinician drawn to the heart, although examination of the cardiovascular system often revealed isolated or minor abnormalities (such as poor quality of heart sounds or occasional extrasystoles) which did not arouse clinical interest. Terminal circulatory failure was common. The correct diagnosis of the cardiac pathology was never made during life in the cases reviewed. The following types of clinical pictures directed the physician's attention specifically to the heart in 20 cases. Congestive cardiac failure was the presenting feature in nine cases. In seven cases there was chest pain thought to originate in the heart or pericardium. Pericardial friction was noted in six cases. Two patients had poor quality heart sounds and electrocardiographic evidence of myocardial damage. Arrhythmias commonly occurred in the group, sometimes being the only feature to direct attention to the heart. Electrocardiograms were taken in 15 cases, and all were abnormal. The history of one patient is presented, which illustrates the difficulty that may arise in the diagnosis of metastatic tumor of the heart. In this case the physician was confident that the patient had died as a result of myocardial infarction in spite of a rather atypical history and evidence that there was a coexistent bronchial carcinoma. The author shows that the postmortem incidence of secondary tumors of the heart and pericardium in this series (10%) compares with that found by several other investigators. Bronchial carcinoma is the most frequent primary tumor.

ANESTHESIA

Induced Hypotension During Anesthesia and Surgery. D. M. Little Jr. Anesthesiology **16:**320-332 (May) 1955 [Philadelphia].

The deliberate induction of arterial hypotension during anesthesia and operation to effect a diminution of blood loss has become increasingly important in the past few years, because some operations are now extremely extensive and others penetrate deeply into the vital structures of the body. Hypotension is induced either by a reduction of the total circulating blood volume or by a decrease of peripheral resistance. The author reviews 27,930 cases in which these techniques have been used and stresses the potential complications. The mortality rate was 1 in 291, and complications occurred at the rate of 1 in 31 cases. Complications and the deaths from induced hypotension are closely related to the degree and duration of hypotension. A modified technique of controlled hypotension has been evolved, which takes advantage of the fact that the level of the systolic arterial pressure that must be obtained in order to provide a relatively bloodless operative field varies tremendously among individual patients. The exact level to which the blood pressure must be lowered, therefore, cannot be foretold prior to operation: the required level can be determined only under conditions of actual operation after suitable posturing of the patient and by direct observation of the bleeding, or lack of it, in the operative field. This optimal level of systolic pressure is usually much higher than the dangerously low systolic pressures of 50 to 60 mm. Hg advocated in the past. A significant reduction in the blood loss from the surgical wound frequently is noted at pressures of 90 to 100 mm. Hg or even higher, and such pressures may represent decreases of only 10 or 20 mm. Hg from the preoperative readings. The thiophanium compound, arfonad, has been used in this modified technique because it produces an evanescent, though potent, depressor response of the arterial pressure. It is therefore possible to give the drug by continuous intravenous infusion, and in this manner to provide variable and graded fluctuations of the blood pressure and thus to achieve minute-to-minute control of both the degree and the duration of the hypotension. This controllability is of further value in that it permits the rapid termination of the hypotensive state at the end of the operation or the rapid abandonment of the technique in the face of inadvertent hemorrhage and similar surgical exigencies.

Use of a Synthetic Analgesic in Anesthetic Premedication: Possibility of Intravenous Administration and Antihistaminic Combination. G. Martinetto. Minerva anest. **21:**86-91 (April) 1955 (In Italian) [Turin, Italy].

Ketobemidone, a synthetic analgesic, was used to prepare 74 patients for general anesthesia, 68 for general mixed anesthesia, 14 for local anesthesia, and 8 for spinal anesthesia. From 7.5 to 15 mg. of the drug were given subcutaneously one hour, or intravenously 10 minutes, before the operation. Patients in whom general anesthesia was to be induced also received at the same time 0.5 mg. of atropine. Regardless of the route of administration, ketobemidone had a marked analgesic and anesthesia-potentiating action, a moderate hypometabolic and parasympathicolytic and sympathicolytic action, and a weak psychodepressing action. Side-effects were rarely observed, anesthesia was induced easily, and reawakening was normal. Sixty-one patients were given ketobemidone combined with 100 mg. of Antistine. This potentiated the preanesthetic action of the analgesic. The author concludes that subcutaneous or intravenous administration of this drug in anesthetic premedication is useful, and that there are instances in which its combination with an antihistamine may prove highly beneficial.

PHYSIOLOGY

The Role of the Pituitary and Thyroid Glands in the Phosphorus Metabolism of the Adrenal Gland During Cold Stress. D. Nicholls and R. J. Rossiter. Endocrinology **56:**547-559 (May) 1955 [Springfield, Ill.].

The phosphorus metabolism of the adrenals was studied after removal of the pituitary in rats that were placed in a cold room for three hours, and in normal rats at room temperature. It was also studied in rats receiving a daily dose of 2-thiouracil in excess of that required for a maximal histological effect on the thyroid and being exposed to cold either for three hours or eight days. In order to prevent death from exposure those exposed to cold for eight days were given a daily dose of 2.5 mcg. of thyroxine in alkaline sodium chloride solution subcutaneously, beginning at the time of the thiouracil treatment. Thyroxine was similarly administered to a group of animals not receiving thiouracil that were also exposed to cold for eight days. The effect of eight days in the cold also was studied in a group of untreated rats. In rats exposed to cold for three hours there was an increase in the incorporation of radioactive phosphorus (P^{32}) into the acid-soluble phosphorus fractions of the adrenals. This increase was abolished by removal of the pituitary. In rats similarly exposed to cold, but whose thyroid function was depressed by the administration of thiouracil, the phosphorus metabolism of the adrenals was increased to the same degree as in normal animals. The increase in the phosphorus metabolism of the adrenals observed after a sojourn of eight days i the cold was still present in the thiouracil-treated rats, but th increase was much smaller than that observed in normal animal The early response in the phosphorus metabolism of the adrena of rats exposed to cold for three hours is caused by endogeno corticotropin liberated from the pituitary. The later response rats exposed to cold for several days depends, in part at lea on the activity of the thyroid.

Comparative Effects of Pamine, Banthine, and Placebos Gastrointestinal Motility: I. Radiographic Study in Eight Ad Subjects Tested When Fasting and After Three Weeks' Admin tration of Agents; II. Radiographic Study in Eight Adult S jects Tested When Fasting and Following the Administration a Standard Meal. W. P. Chapman, S. M. Wyman, J. O. Gag and others. Gastroenterology **28:**500-518 (April) 1955 [Ba more].

Single doses of 5 and 10 mg. of methscopolamine (Pam bromide and of 50 and 100 mg. of methantheline (Banth bromide were given on a fasting stomach to eight men. E ounces of barium suspension were administered orally to t persons one hour later. Four hours after the administra of the drugs and three hours after the taking of the barium r roentgenograms of the stomach and of the intestines were m The effect of the drugs on the time of gastric evacuation an the transport of barium along the intestine in these eight was compared with that of placebos. Methscopolamine methantheline in two different single therapeutic doses ca about the same significant delay in the forward moveme barium along the intestine as compared to the findings placebos. The results were different for the time of g emptying in that only methantheline in doses of 100 mg. c a significant delay in the evacuation of barium from the sto Repeated tests following the administration of 50 mg. of me theline and 5 mg. of methscopolamine for three weeks indi that the continued use of these drugs did not modify their on gastric motility. Methantheline caused more dryness mouth than did methscopolamine or placebos, but afte drugs had been given for three weeks this side-effect had ished so that it was no more pronounced than in the meths amine and placebo tests. Of the eight men experiment seven were healthy and one had a chronic duodenal ulce results in the latter patient were not different from those remainder of the group. Clarification of the therapeutic tiveness of methantheline and methscopolamine in peptic must await long-term studies in which these drugs are co ith placebos, antacids, and other medications. In additional periments, one half hour after the administration of methaneline and methscopolamine and one half hour before the swalwing of the barium, the eight men were given a standard meal nsisting of oatmeal, two pieces of toast with two pats of tter, two servings of jelly, one glass of milk and, at the end the meal, one glass of orange juice. The movement of barium the same person following methscopolamine, and on two other casions, a placebo, and methantheline were compared. The al made no difference in the effects of the drugs on gastric acuation in either dose compared with that of the placebo. On other hand, the drugs in either dose had significantly more laying action on intestinal motility during the fasting tests in when they were given with the meal. In the meal tests thscopolamine in either dose caused more diminution in estinal motility than did the placebos while the intestinal ults with methantheline in either dose were not significantly ferent from the findings when the placebo was given. The only luence of the meal on side-effects was to eliminate the sigicantly greater incidence of dry mouth that was noted in the ts with 50 mg. of methantheline than in the tests with a plao performed under fasting conditions. The inclusion of the al in their tests leads the authors to conclude that a sounder sis has been established for the pharmacological assessment of se drugs in man.

ucagon, Hyperglycemic Glycogenolytic Pancreatic Hormone. Clément. Presse méd. **63**:746-748 (May 18) 1955 (In French) aris, France].

Glucagon is a hormone closely resembling insulin in its compoon and chemical properties. It is secreted by the alpha cells the pancreas and acts as an antagonist to insulin, which is reted by the beta cells. Separation of the two hormones, howr, is difficult, and before glucagon was isolated, its hypercemic effect was ascribed either to a paradoxical action or to presence of an impurity in insulin preparations. Glucagon oduces hyperglycemia by mobilizing the liver glucose, and the ensity of the hyperglycemic response depends on the quantity liver glycogen available. This glycogenolytic property has l to its designation by some authors as "hyperglycemic glycoolytic factor." Glucagon secretion is stimulated by hypocemia and therefore by insulin. In fact, both hormones paripate in the maintenance of the blood sugar level and an excess one leads to the reactional secretion of the other. Glucagon, inephrine, and the hypophysial somatotropic hormone all ssess the property of raising the blood sugar level, but the panatic factor is effective in the absence of the adrenals and the pophysis. The significance of these findings in their relation the production and treatment of diabetes mellitus and renal abetes has not yet been fully determined. The presence of a tain amount of glucagon in insulin does not seem to aggrate diabetes or to hinder its treatment, but experience has shown at when pure insulin is used, the doses needed are slightly aller and insulin resistance is easier to overcome. Attempts to glucagon in the treatment of glycogenic liver disease have en disappointing, but certain forms of hypoglycemia, in which alpha cells of the pancreas are aplastic or reduced in numr, may prove to be responsive to glucagon replacement therapy.

iet and Life Span. M. Silberberg and R. Silberberg. Physiol. v. 35:347-362 (April) 1955 [Washington, D. C.].

The duration of life is determined by the interaction of genetic d environmental factors, both of which influence the rates growth, development, and aging.' Environment may permit intrinsic life potential to assert itself to the fullest extent may increase the hazards to life and thus cause premature ath. Dietary influences may exert both kinds of effects by fecting the course of disease as well as the processes of growth, velopment, and aging. In a variety of lower animals, life may prolonged by restriction of food. This is associated with faraching reduction of body size, vital activities, or both to which ese species can adjust themselves. Higher species with their omplex organization, however, are, particularly during the period of growth, less adaptable to drastic food restriction than the lower animals. Moderate dietary restriction favors longevity during certain periods of life. The exact age at which restriction should be instituted in order to accomplish an optimal effect has yet to be determined. In mammals this date may coincide with the stage of development of the long bones when regressive changes begin to overcome the growth of the epiphysial cartilage. Although there is no evidence that under these conditions the absolute life span can be prolonged, the average duration of life may be increased either by prevention of disease or by retardation of age changes or both. Severe underfeeding immediately after weaning is incompatible with normal growth and development and may even result in increased mortality early in life, particularly in girls, but the mortality of surviving persons is decreased, and some survivors will live to extreme old age. This induced longevity, however, does not prove that undernutrition so drastic as to cause stunting of growth is desirable from a biological point of view. Large dietary protein or carbohydrate allowances apparently do not worsen the prospects as to longevity provided no secondary deficiencies will be created. A high level of dietary fat has, as a rule, adverse effects on the life span. Apparently somewhere between the extremes of undernourishment and dietary enrichments lie those regimens that are optimal for longevity. Ideally, these should permit a good and uniform but not necessarily fast rate of growth and development early in life, and should, in order to avoid the injurious effects of overnutrition, subsequently stay at a low level that should still be adequate to permit a person to live not only a long but, at the same time, an active and useful life. Retardation of growth as such does not seem to contribute materially to longevity just as acceleration of growth as such does not appear to contribute materially to the shortening of the life span. On the other hand there are indications that the duration of life is influenced more by conditions to which the effect on growth is incidental and which prevail also when growth has passed its most active phase. This agrees with the concept that growth and longevity are not mutually interdependent but are coordinated phenomena governed by the same metabolic principles.

INDUSTRIAL MEDICINE

Clinical, Pathogenetic, and Diagnostic Problem of Silicotuberculosis. M. Crepet and G. Pescetti. Minerva med. **46**:710-720 (March 17) 1955 (In Italian) [Turin, Italy].

In a series of 124 patients who had silicosis as the result of exposure to silica-laden dust for 5 to 40 years, 18 had stage 1 silicosis; in 8 the disease was in an intermediate phase between stage 1 and stage 2; 60 had stage 2 silicosis; and 38 had stage 3. Bacteriological, laboratory, and radiological findings indicated that the rate of the tuberculous complication in such patients increases as the silicosis progresses. Active tuberculosis was not found in any of the patients of the first two groups, but was present in 12 of those with stage 2 silicosis in whom the common clinical and radiological aspects of tuberculosis (infiltration, lobitis, and caseous adenopathy) were seen instead of the productive or ulcerofibrous features that are characteristic of silicotuberculosis. It is suggested that the term "tuberculosilicosis" rather than silicotuberculosis be used for such patients. Active tuberculosis was found in eight patients with stage 3 silicosis and was characterized by evidence of parenchymal ulcerations on the roentgenograms. In six of the eight patients the presence of tuberculosis was confirmed by the presence of tubercle bacilli in the sputum. Parenchymal ulcerations in patients with stage 3 silicosis need not always indicate a superimposed tuberculous infection. In 50% of the patients with ulcerations, these were only apparent (areas of bullous emphysema) or they were caused by such factors as abscesses or colliquation owing to ischemic necrosis. Most of the patients with stage 3 silicosis (73%) did not show signs of tuberculous or other infection. The authors conclude that the transition of silicosis from the nodular to the massive stage can take place without the superimposition of a tuberculous infection or of any other infection.

progress in the control of all communicable diseases, many of which occur much too frequently in the United States to permit any complacency.

VIRAL DISEASES

Perhaps of greatest concern at the moment is the viral diseases problem. Virology, as an integrated biological science, is less than 10 years old, and knowledge of the behavior of the ultramicroscopic viruses, both in man and his environment, is still fragmentary. The viral diseases of man, of which more than 40 are known, include such major epidemiological problems as the upper respiratory disorders typified by the "common cold," poliomyelitis, infectious hepatitis, arthropod-borne encephalitis, psittacosis, rabies, yellow fever, measles, mumps, and smallpox, and, among animals, such diseases as foot-and-mouth disease, rinderpest, distemper, and myxomatosis.

Poliomyelitis.—The problem of poliomyelitis in the United States cannot be accurately measured by the more than 36,000 cases reported in 1953 or by the 58,000 cases reported in a high epidemic year such as 1952. This baffling disease is now distributed over the entire United States, and its incidence has been increasing for more than a decade. The long crippling effects following paralytic cases, and the hysteria that accompanies an epidemic, are matters of both local and national concern. Poliomyelitis also is increasing in many other parts of the world, which suggests that we may be witnessing a world-wide pandemic, the end of which is not yet in sight.

Great strides have been made in determining the characteristics of poliomyelitis and toward the development of an effective vaccine for its prevention. This progress is encouraging and allows the control problem to be approached with increasing intelligence, but it does not justify any lessening of efforts to uncover the basic epidemiological principles that govern its occurrence and spread. This disease will continue to be an enigma until these principles are determined. Also, the complex nature of poliomyelitis presents many difficult diagnostic problems, the solution of which requires more efficient methods of laboratory diagnosis.

Viral Hepatitis.—Infectious hepatitis, another viral infection, has increased in incidence at a rapidly accelerating rate during the past few years. In 1951, a total of 44 states reported 7,349 cases, principally in local outbreaks; in 1952, after the disease had been added to the list of nationally notifiable diseases, 46 states reported a total of 17,428 cases; and, in 1953, with reports in from 47 states, the annual incidence reached 33,700 cases. For 1954 the preliminary figures show a total of 50,000 cases reported in the 48 states. The viral nature of infectious hepatitis and of related serum hepatitis was discovered only recently, and control measures have not yet been defined, although for infectious hepatitis, gamma globulin has been effective in reducing the occurrence of secondary cases among family contacts. While person-to-person spread probably accounts for a large proportion of cases of this disease, common-source outbreaks through contaminated food or water also occur. We know that serum hepatitis is transmitted by way of blood or blood products, but many aspects of the relation of serum hepatitis to infectious hepatitis are puzzling. Mechanical transmission as a means of spread of these two highly infective diseases cannot be overlooked in this day of frequent injections and blood transfusions.

Arthropod-Borne Viral Encephalitides.—The arthropod-borne viral encephalitides present a complex epidemiological picture. In addition to man, these viruses affect horses, mosquitoes, mites, birds, mice, snakes, and probably other animals. The precise role each of these species plays in the ecology of the encephalitis viruses is not known. Man appears to be only an accidental host in a complicated life cycle among other animals that are the primary hosts.

In some years, the incidence of the disease in man is characterized by a few scattered sporadic cases, while in other years, in some particular area, an outbreak of epidemic intensity will occur, involving both man and horses as well as other animals. An episode of this nature took place in the summer and fall of 1952 in the Central Valley of California, when some 800 human cases and 400 equine cases were recorded. The most recent outbreak occurred in 1954 in a county on the U. S.—Mexico border. The first case occurred in July, and by the last week of August the epidemic had reached its peak. Although only 373 cases were recorded through official reporting channels, medical personnel sent to the field during the outbreak estimate that there were probably from 800 to 1,000 cases among the population of the county. A total of nine deaths occurred during the epidemic. From a previous 10 year history of an occasional reported case of encephalitis, this disease spurted to epidemic proportions within the short space of less than two months, taxing both medical and public health facilities of the area.

In addition to our native encephalitides, there are other types, such as Russian, Japanese, and Venezuelan, which occur in various parts of the world, and it is not known what forces in nature may introduce these viruses among our insects and animals; nor are the factors known that produce proliferation of the viruses, with ensuing infections among man. Indeed, these diseases are of such complexity that many different approaches undoubtedly will be necessary to elucidate and disentangle the host-virus relationships.

Psittacosis.—Psittacosis, a viral disease that produces atypical pneumonia, has shown a marked increase in recent years. From an average of some 28 reported cases per annum from 1945 through 1951, the incidence rose to 135 and 169 in 1952 and 1953 respectively. In 1954, the annual total increased to 444 cases. The disease is present among parakeets, which recently have become a favorite among household pets, and is also present among some of our domestic flocks of fowl. A sick parakeet and a stubborn respiratory disease in a member of the household is sufficient reason for suspicion of psittacosis. Unfortunately, no immunizing agents have been developed that can be used against psittacosis in either bird or man. Its control involves cooperation of owners, producers, and distributors in treating or destroying diseased birds, as well as education of the bird-loving population.

Rabies.—Rabies is one of the frightful infections from which man has suffered since ancient times. Few deaths re reported each year, but the majority are among chil- ren 5 to 14 years of age, an age group of enormous motional appeal in any community. The administration f the long series of injections necessary to prevent rabies llowing a bite from an infected animal is a particularly isagreeable procedure and is fraught with danger. The servoir of the disease is in dogs and in various species f wild animal life. Recently the list of animals known harbor rabies was increased by the discovery of the irus in insect-eating bats. This finding indicates that the servoir of the disease may be much larger than hereto- re had been suspected and points to the necessity of rther investigations to determine all animal species at could be responsible for transmitting rabies to do- estic animals and man.

Smallpox.—Smallpox, another ancient viral infection, reported every year, but confirmed cases of the dis- se are rare. The last outbreak of any consequence in e United States occurred in New York City in 1947, hen one imported case gave rise to 11 subsequent cases nong those in close contact with this patient. Few resi- nts of that city will ever forget the consternation used by this episode, which disrupted and overtaxed e normal public health services of the city. Universal ccination may be an accepted principle, but it needs ly an outbreak of this nature to show that vaccination not universal practice.

Yellow Fever.—Yellow fever, one of the most viru- nt of the virus diseases, has been eradicated from the nited States. An indigenous case of this disease has not en reported in this country for 50 years, and recur- nce of yellow fever here in epidemic form is looked on as only a remote possibility. Nevertheless, the edes aegypti mosquito, the urban vector of yellow ver, abounds in our southern states. This, coupled with e fact that the reservoir of the virus persists in the ani- als of the Central and South American jungles from hich the disease periodically "spills over" into urban pulations of port cities, makes the chance that yellow ver may be introduced in this country one that can- ot be ignored. It justifies not only the strict enforce- ent of quarantines but also the keeping in readiness of plan for immediate eradication should the need arise.

"Common Cold."—The last of the viral diseases to be nsidered here is that complex infection known as the ommon cold" with which everyone is familiar. This lment, although considered to be one of the less severe fections, is the source of a great deal of human misery nd discomfort. It is also one that causes enormous onomic loss. Because the common cold is not a re- ortable disease, only generalizations regarding this loss an be made. If we assume, for instance, that the 60 mil- on workers in the United States lose an average of only ne day per year because of a "cold," the resultant loss the equivalent of 230,769 man-years of work, or, tated differently, a loss to our labor force of a quarter illion workers a year. Furthermore, if we assume a onservative annual wage of $2,500 per worker, the total nnual loss amounts to over 500 million dollars ($576,- 22,500).

Pneumonia and Influenza.—The history of pneu- nonia and influenza deaths in this country has been marked by periods of high incidence, although the overall trend has been downward since the great pandemic of 1918. These diseases represent a group of infections caused by both viral and bacterial agents, and, although the deaths due to pneumonia and influenza are at the lowest figure in the history of this country, the rate is still around 32 per 100,000 population, a rate that was achieved in 1949 and that in succeeding years has remained the same. Thus, these diseases rank as a major cause of death. Pneumonia is an important secondary cause of death in other pathological conditions and injuries. In 1940, the most recent year for which a national study of joint causes of death is available, it was found that for every 10 deaths for which the primary cause was pneumonia or influenza, there were 6 additional deaths in which pneumonia was a secondary cause.

BACTERIAL DISEASES

The diseases next to be considered are those caused by bacteria. These pathogenic agents, through infection of the heart, kidney, brain, and blood, play an important role in initiating degenerative diseases during the productive years of life, and much remains to be learned about the mechanisms of the infective processes. It is against these specific infections that the antibiotics have been so dramatically effective; however, with the increasing and not too discriminating use of the antibiotics, the emergence of resistant strains of pathogens in now posing problems not only to clinicians and hospitals but to the general community. Resistant strains of tubercle bacilli are now a well-known phenomenon. Resistant strains of the micrococci, considered to be the most important and common cause of bacterial infections, may be acquired from symptomless carriers. Control of these strains of bacteria, as has been pointed out by workers in this field, requires extended knowledge concerning the fundamental nature of the mechanisms involved in the mode of action of the antibiotics and of the factors involved in the development of resistant strains. Equally important is further clarification of the epidemiology of infection by both the resistant and the nonresistant strains.

Streptococcic Sore Throat and Scarlet Fever.—Streptococcic sore throat and scarlet fever cases have been reported in increasing numbers in recent years, although, like pneumonia and influenza, the long-time trend has been downward. With the advent of antibiotics, the incidence of scarlet fever and streptococcic sore throat fell steadily from its last peak of 200,539 cases in 1944 to a low of 64,494 in 1950. Since that time, there has been a continuing upward trend in the annual number of cases, reaching totals of 85,151 in 1951; 113,677 in 1952; and 132,935 in 1953. This past year (1954) nearly 145,000 cases were reported. This is the highest annual total recorded since 1945. Could the recent increase in the number of reported cases be an indication that the antibiotics, while effective as a curative, have not been effectual in preventing transmission of the disease?

It is of interest to note that less than a hundred years ago this invading Streptococcus was among the leading causes of death in children. Formerly fearful and highly fatal maladies, these infections today are considered to be mild and innocuous; nevertheless, the role that they play in subsequent valvular heart disease is of particular concern. Each year some 35,000 deaths are attributed to heart disease of rheumatic or pyrogenic origin.

Epidemic Cerebrospinal Meningitis.—The last epidemic of cerebrospinal meningitis in this country occurred between 1942 and 1947, reaching its peak in 1943-1944. During the epidemic, a total of some 56,000 cases was reported, with a mortality of 9,000 or roughly 20%. Since the 1948 low, when only 3,376 cases were reported, there has been an annual increase to a total of 5,077 cases in 1953. During the period 1948-1951, approximately 15,000 cases were reported, together with 4,000 deaths, yielding a case fatality rate in excess of 25%, which is much higher than the 5% fatality rate reported for cases of this disease occurring in the Army during World War II. The high civilian rate, when compared to the military, may be a reflection of the incidence of the disease in a different age distribution, underreporting of civilian cases, and delays in obtaining medical care and institution of proper therapy. The epidemiology of epidemic cerebrospinal meningitis has not been fully delineated. Its rise to an epidemic peak is more deliberate than that of other communicable diseases. Within an epidemic cycle there is an annual waxing and waning, with increasingly higher incidence in successive years, until the epidemic reaches its maximum. The ascent requires from two to five years, and the decline follows the same pattern.

Diarrheal Diseases.—The diarrheal diseases continue to be a public health problem of considerable magnitude. These are not nationally reportable diseases, and one can only guess the total number of cases. We know, however, that during the five years from 1947 to 1951 more than 35,000 deaths from these infections were recorded among children under 5 years of age. Epidemic diarrhea of newborn infants caused some of these deaths, but approximately 90% of them occurred among children over one month of age. These diseases are amenable to control, since most of the deaths have occurred in substandard areas where sanitation falls below the national average; however, many of the etiological agents are unknown, and the epidemiology of the known pathogens is not fully understood. Particularly in need of clarification are relationships between diarrheal diseases and parasitic infections. The key factors in sanitation that are responsible for the spread of these diseases are yet to be discovered, as is the role of familial relationships in person-to-person dissemination.

Other gastrointestinal infections of bacterial origin, bacillary dysentery, and typhoid and paratyphoid and other salmonelloses, are of varying importance today in the United States. Typhoid has been declining constantly since the turn of the century and in 1951 reached a low of 2,128 cases; however, in 1952 and 1953 the numbers of reported cases were slightly in excess of this figure. On the other hand, reports of paratyphoid and other Salmonella infections have shown a gradual increase from 712 cases in 1944 to 3,946 in 1953. Incidents involving food poisoning due to bacterial contamination occur with a frequency not warranted by our reputed high standards of hygiene and long experience with these pathogens. Outbreaks of amebiasis, an associated enteric disease caused by a protozoal agent, occur with increasing regularity. Between 3,000 and 5,000 cases of amebiasis have been reported annually since 1944. The fact that outbreaks of these various enteric diseases can and do occur, requiring immediate intensive attention for their control, indicates that there can be no letup in the attention we give to this group of infections.

Diphtheria.—The low incidence of diphtheria, with only 2,355 cases in 1953 for the nation as a whole, is not an accurate index of the importance of the disease, for outbreaks continue to occur in which the incidence rates are extremely high. The level of immunity is not known for most of our communities, and when or where an introduced case of diphtheria will result in an outbreak cannot be accurately predicted. An example of the "flaring up" of diphtheria is the outbreak in one of the counties of a western state that occurred in the early spring of 1953. This county, with a population of 42,000, had had very few cases of diphtheria, three or less per annum, in the previous 10 years. In January of 1953, a single case was reported, and it was followed in the succeeding weeks of February and March by a total of 52 cases. Thus, after a long period of quiescence, an annual attack rate of over 125 cases per 100,000 population occurred.

In November, 1954, a county on the Ohio River with a diphtheria-free history of a period of at least 10 years, experienced an unusually severe outbreak. In this county of some 9,500 inhabitants, a total of 24 cases was reported by local physicians, and an additional 11 cases were discovered by medical personnel investigating the epidemic. Four of the cases terminated fatally, and another child was left with a serious myocarditis. Preliminary findings in a survey of the immunization status of the school children in this county indicated that perhaps only a third were adequately protected against the disease.

Diphtheria is a disease of concern not only to the public health authorities who campaign the year round for immunization of preschool and school children but also to the clinician, who always must consider the possibility of the disease among his patients.

Tuberculosis and Venereal Diseases.—Tuberculosis and the venereal infections have been and are still being subjected to intensive control efforts by federal, state, and local health departments. Progress has been made in reducing both of these diseases; nevertheless, they still remain of great importance insofar as the general health of the nation is concerned. It is estimated that at present there are 1,200,000 cases of tuberculosis in this country, 400,000 of which are active and 800,000 inactive but under medical supervision. Although the number of deaths annually both here and abroad has declined at an accelerated rate in recent years, the case rate shows no similar decline. More than 100,000 newly discovered cases have been reported annually in the United States during the past 10 years. This high level of reported cases may be due to more effective and earlier case finding by health workers and may obscure an over-all decrease. We must, however, agree with the

British observers that, so long as active cases are reported in such impressive numbers, it cannot be assumed that tuberculosis is a conquered disease.

Disability and death from the venereal diseases also have been diminishing in recent years. Nevertheless, the magnitude of the current problem can be gauged by the more than 150,000 cases of syphilis and some 250,000 cases of gonorrhea that were reported for the civilian population during 1953. These are only the reported cases, and it is certain that many infections remain undetected. Practical reliable laboratory diagnostic tests are yet to be discovered. There are no known immunizing agents against either syphilis or gonorrhea, and, until such are discovered, intensive case-finding activities, education of the public, and prompt administration of therapy must continue as the best means of controlling the spread of these infections among our population.

Dermatomycoses.—The fungous diseases of the skin constitute another group of infections of immense importance in this country, not only because they impair the health and happiness of a large portion of our population but also because, under circumstances of stress, they can be disabling diseases. Dermatophytosis (athlete's foot), for example, is a widespread and harassing ailment. It is highly infectious, and its cure may require years of treatment. During World War II, 8% of all hospital admissions among the armed forces were for cutaneous disease, and dermatophytosis was second on the list. Among the civilian population, it is the athletically inclined high school and college students especially who incur a high incidence of the disease, and they are the members of our armed forces of tomorrow.

Tinea capitis, another disease in the same category, is a troublesome problem to the school, to the child, and to his parents. In the southwestern states there is a newly discovered type of epidemic tinea capitis that affects both children and adults. It is difficult to detect because the lesions are often minimal, and it is a stubborn disease to cure. It may persist for years, and untreated cases frequently result in permanent baldness.

There is no information on prevalence of fungous diseases, but undoubtedly the total number of infected persons is very high. Approximately 3 million dollars was spent in 1953 on across-the-counter packaged medicaments for dermatophytosis alone, and this does not include remedies prescribed by physicians.

COMMENT

The foregoing discussion has been concerned with some of the more important communicable disease problems of long standing. In addition, there are others demanding attention. Clinical and epidemiological studies are continually expanding our knowledge of disease entities whose etiologies previously have been obscure. Determination of the prevalence, geographical distribution, and modes of spread of these newly identified infectious diseases is a continuing problem of present and future years. With advances in methods of clinical and laboratory differentiation, cases of toxoplasmosis, leptospirosis, Q fever, and systemic fungous infections such as histoplasmosis, blastomycosis, and coccidioidomycosis are being reported in the medical literature with increasing frequency. Toxoplasmosis, a protozoal infection that infants may contract from their carrier mothers, causes mental retardation and blindness. Leptospirosis, a spirochetal disease found in many parts of the world including the United States, is carried by the rat, dog, cow, and other animals. It may be contracted in contaminated waters and may or may not be accompanied by jaundice. Q fever, a pneumonia-like infection, occurs along the Pacific Coast and in the southwestern sections of this country. The systemic fungous infections, which in their acute and chronic stages are frequently misdiagnosed as tuberculosis, are endemic in many areas of the country. Others of the ill-defined syndromes of today undoubtedly will be differentiated and traced to specific etiological agents by use of improved diagnostic methods.

Each facet of the problem of infectious diseases presents a continuing challenge. It is essential to be constantly alert to prevent the reestablishment of the dread diseases of the past; to develop control measures for those diseases, particularly viral infections, which today spread without restraint; to apply with greater effectiveness those preventive measures that are available today; and to continue to expand knowledge of diseases of obscure etiology.

It is obvious that the conquest of the communicable diseases is one of the compelling problems of our time. The principal victims of these diseases are not the older men and women who look forward to a future of quiet and uneventful pursuits; they are the young and vigorous segments of the population on whom the present and future productive power of the nation depends. The children and younger men and women must have a top priority in our health programs if we are to assure the vitality and stamina of our future adult populations.

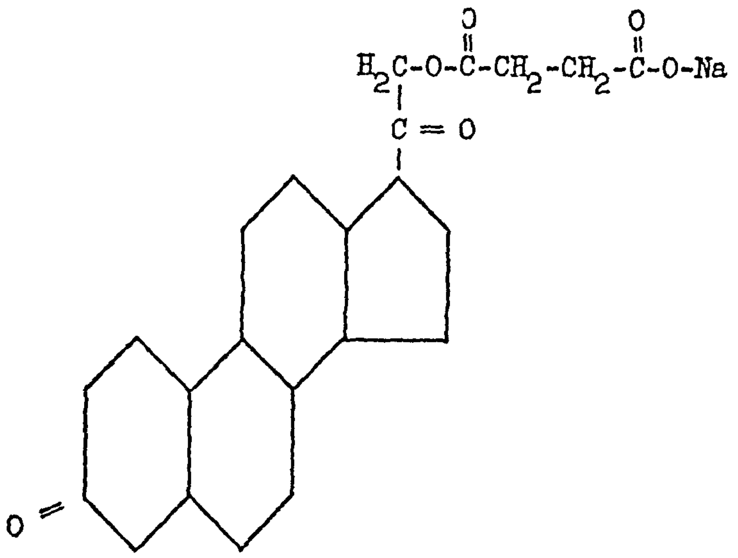
50 Seventh St. N. E. (5).

Dangers in New Dentifrices.—Since the addition of antienzymes to the various commercial dentifrices physicians and dentists are encountering a new oral lesion. This entity has taken many bizarre and complicated forms, and its correct diagnosis necessitates inquiry as to the patient's use of antienzyme dentifrices. The symptoms have been alarming to most patients; a few developed neurotic fears, such as cancerphobia, before the correct diagnosis was established. Many people are using antienzyme dentifrices without developing any . . . symptoms or lesions. It seems, however, that persons using antienzyme dentifrices should use one commercial brand, rather than switch from one to another, because . . . changing brands seems to build up or produce a sensitivity to the antienzyme. It is possible that the antienzymes, in addition to neutralizing the enzymes necessary to bacterial growth, also neutralize some of those enzymes which are necessary to the existence of the normal oral epithelium, thus producing a condition which causes a degeneration of the surface epithelial cells. In no way do I discount any of the merits of antienzyme dentifrices, but only wish to point out a new syndrome in the array of oral conditions. Many patients using the antienzyme dentifrices have stated that when they began using them they noted pain in the tongue and mouth which gradually disappeared on continued use of the dentifrice. Some patients have noticed the oral syndrome only after changing from one brand to another. Some have been unable to tolerate any type of antienzyme dentifrice.—Lieut. Col. W. B. Simms (DC), U. S. Army, Oral Lesions Caused by Antienzyme Dentifrices, *United States Armed Forces Medical Journal,* July, 1955.

USE OF STEROID ANESTHESIA IN SURGERY

Frank J. Murphy, M.D., Neri P. Guadagni, M.D.
and
Francis DeBon, M.D., San Francisco

In the course of investigation of many different steroids Selye [1] noted in 1941 that certain of these substances produced varying degrees of depression and anesthesia in laboratory animals. This was only of academic interest until recently when Laubach and associates [2] studied a large number of new water-soluble steroids to determine their anesthetic activity. Of the substances tested, it was found that 21-hydroxypregnanedione sodium succinate (see figure) was the most promising. The compound was studied for its possible undesirable side-effects on animals, and its therapeutic index was established. This drug was found capable of anesthetizing laboratory animals with a wide margin of safety. In anesthetic doses it did not produce significant hormonal effects and did not cause salt retention or damage to any vital organ.[3] Gordan and associates [4] studied the effects of this compound, known as Viadril, on the cerebral metabolism of humans and reported metabolic changes identical with those of barbiturate anesthesia. These studies culminated in the successful trial of this drug, with nitrous oxide supplement, as the anesthetic for a prefrontal lobotomy. Encouraged by these findings, it was decided to give Viadril a clinical trial as a basal anesthetic for surgery at the University of California School of Medicine.



Structure of 21-hydroxypregnanedione sodium succinate (Viadril).

TECHNIQUE

Viadril is a white, crystalline substance that is soluble in water and has an alkaline reaction, the pH being 8.5 to 9.8. It has been administered in solution in either distilled water or isotonic sodium chloride solution. In either case, a 2.5% solution is freshly prepared. An intravenous drip of 5% glucose in distilled water is started in a vein of the arm. This should run freely. During administration of Viadril, the stopcock is left wide open. The Viadril solution is injected into the intravenous tubing at a point some distance from the arm, so that mixing and dilution take place in the tubing before the needle is reached. The dosage required varies with the weight, age, and physical condition of the patient as well as with the expected duration of the procedure. In the majority of our patients a total dose of 1.0 to 1.5 gm. was used (40 to 60 cc. of the 2.5% solution). The injection takes place slowly, so that the drug is washed into the vein with a large amount of solution. We have estimated that the Viadril solution does not enter the vein in a strength greater than 1.25% and usually in a much higher dilution than this. Generally, we have made our injection into the median cubital vein of the arm rather than in the leg veins, since thrombosis is more likely to occur in the latter site. Occasionally a patient will complain of pain along the course of the vein used, but this has been eliminated by reducing the injection rate. Approximately five minutes is required to give 1,500 mg., and an additional five minutes is allowed before the patient is considered to be ready for further manipulation.

Although we do not use a standard formula for preanesthetic medication, the average adult comes to the operating room after having had 50 to 75 mg. of meperidene (Demerol) hydrochloride, and scopolamine or atropine in the appropriate dosage. Thus, the patient is not heavily premedicated or drowsy upon arrival in the operating room. This premedication has not been altered for patients receiving Viadril.

COMMENT

Viadril was used in 125 patients for basal anesthesia in a variety of surgical procedures (see table) and in 3 patients for sedation during regional anesthesia. The characteristics sought in all anesthetic agents are a wide margin of safety, reversibility of action, and lack of side-effects. The anesthetic drug is then judged on its ability to produce amnesia and sleep, to abolish pain, and to obtund reflexes and relax skeletal muscles. In the lightly premedicated patient Viadril produces sleep in 5 to 10 minutes after administration of the drug has been initiated. This is a smooth, quiet process devoid of any excitement phase. In a typical case the patient is then intubated or an oropharyngeal airway is inserted and a nitrous oxide–oxygen mixture of 3:1 is administered. Meperidine hydrochloride and muscle relaxants are given as required.

From the Department of Anesthesiology of the University of California School of Medicine.

Read in the Symposium on New Agents and Methods for Analgesia and Anesthesia before the Section on Anesthesiology at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

The compound used in this study was supplied as Viadril by Pfizer Laboratories, Division of Chas. Pfizer & Company, Inc., Brooklyn, N. Y.

We have tabulated our results to allow analysis of the fects of Viadril and to compare it with other basal anesetic agents. Forty-nine of the patients studied were men d 76 were women. The age groups of the 125 patients e listed below.

Age, Yr.	No.	Age, Yr.	No.
1-10	0	41-50	37
11-20	4	51-60	22
21-30	15	61-70	18
31-40	22	71-80	7

our patients, 96% required surgical procedures last- more than one hour. For these patients, a dose of 1.0 1.5 gm. of Viadril was utilized. For shorter procedures, ser doses are under study to allow the patient to re- ond promptly after completion of the surgery. The ration of anesthesia for the patients is listed below.

ration, Hr.	No.	Duration, Hr.	No.
0-1	5	5-6	11
1-2	20	6-7	12
2-3	28	7-8	2
3-4	30	8-9	1
4-5	15	9-10	1

The analgesic properties of Viadril are of interest. At our hospital, when using thiopental sodium and nitrous oxide anesthesia, we customarily limit the barbiturate to 250 to 500 mg. and then supplement it with intravenously given meperidine hydrochloride to control pain. We were therefore able to assess the analgesic potency of Viadril by noting the amount of meperidine hydrochloride necessary as a supplement. The amounts of meperidine hydrochloride used were found to be less than would have been expected had thiopental sodium been used (see table). The great individual difference in susceptibility of patients to opiates makes this property difficult to estimate accurately, but after using Viadril it is our firm clinical impression that it produces a definite analgesic state far greater than that produced by the barbiturates. Moreover, we believe that it potentiates the effect of opiates in both analgesic effect and respiratory depression.

The table shows the amounts of relaxant drugs used in our series. These amounts are considerably smaller than we customarily find necessary when employing thiopental sodium and nitrous–oxide anesthesia. An interesting finding is that, although respiratory depression is not a prominent effect of Viadril, unless considerable amounts of narcotics have also been given, most patients under its influence allow their respiration to be controlled with great ease. This has been found very advantageous in chest surgery, particularly when a quiet field is required. These properties have contributed to the diminished amounts of muscle relaxants used. We have noted that the drug when used in the dosage described above appears to have its maximum effect for a period of approximately two hours. At the end of this time it may be necessary to administer either meperidine hydrochloride or more Viadril—the latter in doses smaller than the original dose.

These various characteristics, namely, control of pain, control of reflexes, and production of relaxation, lead us to classify Viadril as a true anesthetic agent probably best compared with tribromoethanol. We have been very pleased with the lack of postoperative depression of patients in cases in which Viadril and nitrous oxide–oxygen anesthesia have been used. It is noteworthy that the majority of patients (100, or 80%) were responsive at the

nety-one patients had an intratracheal tube inserted. is merits some discussion, as it illustrates the ability Viadril to obtund reflexes, particularly those of the arynx and the larynx. It is easily possible in most innces to intubate a patient without relaxants, once the adril sedation is effective. It is interesting to note that, the laryngeal structures are stimulated or traumatized an unsuccessful attempt at intubation, there may be a nsient laryngospasm that promptly disappears sponneously and permits respirations to resume before any rm has been done. After the intratracheal tube is in ace, there may be some attempts at coughing, but in ost cases these are short-lived and regular breathing is stored in less than a minute. The administration of the trous oxide–oxygen mixture during this time also plays part. In more resistant patients, with very active cough flexes, small doses (25 to 50 mg. administered intranously) of meperidine hydrochloride have never failed calm the patient. With regard to obtunding these rexes, it may be noted that, during thyroidectomies perrmed with Viadril and nitrous oxide–oxygen anesthesia ut without intubation, we have observed occasional oughing but never laryngospasm when the surgeon was timulating the trachea by pressure or traction.

end of the procedures. The response consisted in reacting to painful stimuli, having active reflexes, or speaking. Bouts of coughing and straining, sometimes observed during light thiopental sodium–nitrous oxide–oxygen anesthesia, which may cause the brain to herniate through the opening in the cranium during certain neurosurgical procedures, have not occurred with Viadril. This property has been useful also in two mitral valvulotomy procedures to effect smooth induction of ether anesthesia by avoiding straining, coughing, and excitement.

COMPLICATIONS

We have noted no complications after the use of Viadril except on three occasions when the administration of the drug was followed by thrombophlebitis in the injected vein. It is particularly interesting to note that in each of these cases the patient had widespread vascular disease and was receiving the anesthetic for an aortogram. It is quite possible that there was also pathology in the vein in which the Viadril was administered, which may or may not have been a contributing factor. We were also interested to note the comparison between these cases and one reported by Lundy[5] in the administration of Dolitrone (5-ethyl-6-phenyl-meta-thiazane-2,dione). Our patients also were prone, with the arms above the head, and it is quite possible that there was pooling of the blood in the vein and that this also helped to account for the thrombophlebitis. We consider it wise, however, never to use leg veins, which are notoriously more prone to thrombophlebitis, as the site of injection.

A minor complaint, noted on several occasions, has been transient pain in the arm during drug administration. However, by slowing the rate of injection this complaint has been eliminated. Some patients have complained of nausea and vomiting after operative procedures in which this drug was used. The incidence is certainly not greater than normally occurs with all surgic procedures, and it seems likely that factors other than t anesthetic are involved. Hypotension has been noted a number of cases soon after administration of Viadr but it has not been considered a serious complication. should be mentioned in passing, however, that this hyp tension is easily controlled by the use of small doses o vasopressor in those cases where the pressure dro lower than is considered safe or where it fails to retu spontaneously within a few minutes.

SUMMARY

On the basis of our experiences with the administ tion of Viadril (21-hydroxypregnanedione sodium s cinate), a new steroid for anesthesia, we have concluc that it is a true anesthetic agent, as evidenced by ability to control pain, obtund reflexes, produce rela tion, and produce sleep, all without depression of v functions. Most satisfactory results have been obtair when administering the compound together with nitr oxide (75%) and oxygen (25%). In many cases it been found necessary or advantageous to add meperid (Demerol) hydrochloride, other agents, or relaxants has also been noted that the latter drugs are all effec in dosages considerably smaller than would have b employed had the patient been receiving thiopental dium–nitrous oxide–oxygen. We believe that this c pound, Viadril, offers definite useful possibilities anesthesiology and that it merits further clinical trial. administration is reasonably safe, and it has a high th peutic index. Preliminary electrocardiographic and e troencephalographic studies, together with kidney liver function tests and hematological examinations, h been performed. These observations are being contin and results will be reported later.

A LOOK AT THE FUTURE OF INTERNAL MEDICINE

Howard P. Lewis, M.D., Portland, Ore.

The swirling progress of 20th century medicine has left us all a little breathless and has created problems that seem to multiply faster than we can solve them. Not the least of these has been the structure of our system of medical education that, one would judge, has opened its seams a bit and is beginning to take water. There is abroad in our land, indeed the whole medical world, a feeling that something should be done about something; but if I sense the situation correctly, we have not yet clearly defined that "something." This medical ferment is inescapably intertwined with the training of our future physicians. It is about this and the connotations it has for the future of internal medicine that I wish to discuss here. I can probably do little to dispel the fog in which we find ourselves afloat, but I hope I can point ou few landmarks that are worthy of thoughtful conside tion.

It has been my pleasant privilege to serve with American Board of Internal Medicine for the past years, and in this position I have had the opportunity sample and study the "national product" of our medi schools and hospitals in a unique, down-to-earth w I have been disturbed by deficiencies I have encounter the more so because they seem to stem as much or m from inadequate training as from shortcomings in candidates themselves. I do not wish to infer that have not seen many young men who are well-train and competent internists, but I do want to make cl that there have been too many who are ill prepared the simple, basic clinical skills and knowledge that I b lieve we have every reason to expect them to posse This experience has made me wonder if our clinical and skill is undergoing atrophy and if we are already

Chairman's address, read before the Section on Internal Medicine at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1955.

nto a captive state where we have come to rely too much ipon the laboratory, the x-ray, and the truly enormous nstrumentation now available. Waning of our clinical ense can only make us less effective as physicians, even hough we may be better as scientific technicians. I have feeling this changing emphasis may be responsible in ood part for our growing attitude of detachment, about hich so many patients complain today.

EW APPROACH TO MEDICINE AND MEDICAL TEACHING

Not many decades ago physicians had little more than ieir clinical knowledge and skill to rely upon, and as a onsequence these were developed to a high degree. till, much of what they thought and did was tinctured eavily with empiricism, because so little was known f the basic bodily functions in health and disease. Into iis milieu came the fresh breath of the upsurgence of iochemistry, physiology, and the other basic sciences, s well as the truly phenomenal expansion of basic and inical research. The changes thus wrought in a few iort years have been startling and of incalculable bene:. Quite naturally, in their train has come the obvious ecessity for a profound reorientation of our whole aproach to medicine and medical teaching.

Our ability to probe ever deeper into the inner workgs of disease has been facilitated in a great measure y the parallel expansion of our laboratory and instruental aids. These have not only grown in number but complexity, so that now it has become impossible for ie person to be familiar with all the scientific details internal medicine, even in a modest way. Such a cirimstance has encouraged men to work in progressively irrowing channels. This subdivision has been particurly noticeable in our teaching institutions. Medical culties are more and more an aggregation of specialists, ith few men around who have the breadth of clinical aining and experience to look at medicine, and for that iatter patients, as a whole. This specialization in one ense has been profitable, because close devotion to a arrow field has enabled men to know it well enough iat they have been able to make all-important fundaiental contributions to our knowledge. With this gain as come a loss in the form of an ever-increasing splinring of the teaching of medical students, interns, and esidents, and a growing overdependence on laboratory nd technical procedures.

It is no surprise, in the light of these changes, to find iat the major weakness of our young internists is in linical examination and diagnosis. In my opinion, this cause for real concern. The capacity to make a enetrating analysis of a history and to competently perrm a thorough and complete physical examination are allmarks of an internist. A broad understanding of the linical manifestations of disease is not a luxury for a racticing internist but a necessity. How else than from ie frame of reference of a well-thought-out clinical imression can laboratory investigation be intelligently aplied, or the nuances of disease be better estimated, tudied, and explored? If we have no clear idea of vhere we are heading in a clinical problem, we are in no osition to take advantage of our advances in the basic nderstanding of disease.

One often hears the opinion expressed that to study and attempt to learn the clinical features of a wide variety of medical conditions is too much to ask of a medical student. It has been proposed that in medical schools mostly basic principles should be taught, with the idea that students will, especially in their postgraduate years, be stimulated to read and learn all they need to know. Many believe, too, that work on the wards can be depended upon to fill most of the major gaps in a student's medical armor. I am afraid these are fond hopes, not probable of realization, except in the case of unusual students. I do not in any way wish to underestimate the value and importance of work on the wards, but my experience still tells me that one of the best groundworks for a future internist is conscientious study of a good textbook of medicine. The argument that such an exercise is a waste of a student's time because "no one can learn it all" is a specious one. The fact remains that while much is forgotten, much is retained to be built upon later. A perspective of medicine is thereby acquired, a broad base upon which rests skill in history taking and analysis, an art the importance of which no one can challenge.

Somewhere along the line, training in the technique and understanding of physical diagnosis has obviously lagged. Why else would young men who appear to be intelligent and highly educable fail to palpate large livers and spleens? Why would they have difficulty seeing—let alone interpreting—obvious precordial pulsations? Why would they fumble in their attempts at simple neurological examination, or why would so many have no clear idea of what structures make up the silhouette of the heart as it is seen in the x-ray? These deficiencies I have seen, and they represent only a sample. They occur too often and are emphasized when such men may be found well stuffed with milliequivalents and versed in electrocardiography. Those who underrate the high importance of physical examination in the study of patients declare that the laboratory, the x-ray, and our instruments of precision give us highly desirable measurable findings and information, of course, not otherwise obtainable. With this I agree. However, our modern passion for measurement should not blind us to the fact, which expert clinicians can clearly support, that clinical examination has much to contribute and in many instances far more than any test or device now known.

If these observations and thoughts of mine have any merit, and again my experience compels me to believe that they have, it is time for us to take stock and determine what may need correction. I think we would find that research has so captured our enthusiasm and interest that we have come to forget and neglect our clinical corpus in the broad sense. In medical schools there is a growing tendency to look upon those whose interests lie mostly in clinical medicine as distinctly "old hat." The feeling is increasing that everyone of merit should be doing research. The excellence of a medical school as a school now appears to be judged more by the papers issuing from it than by the quality of its teachers.

Research experience as an integral part of the training of a resident has come to be regarded highly in some quarters, and it is interesting to see how many young men have included a year of research fellowship in their training. Sometimes, I suspect, this fellowship year is for the purpose of gaining a foothold in the institution where resident training is sought. I have often wondered how close these men get to their problems, particularly when they are a member of "a team." There is no doubt of the value of research in the nurture of the critical mind; however, it is not the only way to develop such an attitude, and I think we are unrealistic if we fail to recognize that only a few have real aptitude and interest in investigation. Does it really seem profitable or logical for a young man, who does not have that interest and aptitude, to spend a year where he functions intellectually not far above the level of a technician? Another disadvantage lies in the fact that many such men must, during their fellowship year, devote most of their energies to a very restricted field. This cuts down their opportunity for broad training to two years. Two years is too little time to produce a polished internist—at least an internist in the proper sense of the word—and three years is barely enough. On the other hand, for those who do have the aptitude and interest in investigation, we should provide every encouragement and opportunity with the hope that they may wish to continue in this path.

FADING CLINICIAN

In the last analysis, anything done about our training programs will be pretty much the responsibility of the teachers in our medical schools and hospitals. The change in our whole structure of medicine makes it important for us to do some realistic thinking about what kind of teachers we want and how we are to select and train them. Any decisions we make in this regard must keep in view two things: that an internist is distinguished from other specialists by his skill in general medical diagnosis and that the vast majority of internists go forth into private practice. It seems obvious then that during his student and house officer days, a budding internist must spend part of his time with ex[illegible] and broad clinicians who can develop in him the [illegible]unded approach to sick people and the clinical skills he will need. With this advantage his experience with his teachers in the subspecialties will be highly profitable, for it is they who will hone his perception and insight to a sharp edge.

The man who is fast fading from our scene is this broad clinician, and in his stead we are substituting the services of men whose main interest and strength lies in the subspecialties. The contribution they make is essential. I would never suggest that it be compromised. It is the exceptional cardiologist, to use an example, who can do justice to a case of spinal cord tumor or the gastroenterologist who can skillfully work his way through a puzzling disorder of the chest. To achieve a proper balance, we must have these broad clinicians, we must make a place for them, and we must train them.

As it is now, the young man interested in an academic life in medicine feels he must have research experience, that he is lost without a "bibliography"—the bigger the better. Research experience is valuable, but I am not convinced that facility in research necessarily goes hand in hand with skill as a teacher. The scramble to get one's name on papers has led to the reporting of no litt inconsequential or incomplete investigation and to t inordinate loading of the authorship of many papers.

If we are to do our job as I see we should do it, will have to take an almost heretical course and deci that we will train some of our apt young men to beco expert clinicians and clinical teachers and others to investigators. The clinical teacher should be free fro the constant pressure to "produce" in an investigat way and be able to devote his efforts to the study of d ease as a clinical problem and the methods by which t sum total of modern medical knowledge can best transmitted to the young men and women who are gro ing up under him.

My feelings on this subject represent those of individual whose overriding interest has long been cli ical medicine and teaching. Yet, I hope I have been ab to keep the problems I have discussed in a reasona perspective. No single plan or philosophy could ever tailored to fit the peculiar needs and characters of ea of our various medical institutions. I have not intend to even attempt to submit such a plan. I have tried to e press an opinion that I hope may be useful, if for more than a point of view, to those of us who have interest in and responsibility for the future of inter medicine.

3181 S. W. Sam Jackson Park Rd. (1).

Radiation from Nuclear Power Development.—The large-sc development of nuclear power from uranium fission will n essarily produce large amounts of radioactive waste having pr erties identical with those produced in nuclear explosions. T radiations are, however, mainly confined to the nuclear react which are the source of heat for nuclear power stations and the chemical plants where the radioactive wastes are extract from the spent uranium fuel. The radiation in the vicinity the nuclear power units can be kept below the internationa agreed safe levels without difficulty by the use of suitable shiel ing. The average radiation dose received by Harwell worke is 0.25 r per annum. This is one-sixtieth only of the level agree internationally as permissible for the radiologically employe workers. . . . The public health problems are thus largely tran ferred to the chemical processing plants. The radioactive was products include radioactive gases such as radiocrypton a xenon; these are at present allowed to escape from the proces ing plants in conformity with safety regulations so that no har can be caused to the neighborhood. It is likely that in the futu they will be bottled and turned to useful purposes. The emissio of gaseous wastes will not increase to any significant extent we develop the atomic power program. The radioactive soli wastes divide into three groups, only one of which presents serious problem. The first group contains those isotopes whic are only slightly radioactive; these are comparable to the natura radioactive elements of the earth's crust and dispersal is a satisfactory method of dealing with this group. The second group comprises the great majority of the radio-elements produced in fission and these decay fairly rapidly. Storage of these materials, for a period of, say, ten years would reduce the activity to a level at which dispersal would be practicable and completely safe. The third group is the one which presents difficulties. It consists essentially of two elements, strontium and caesium. Each of these has an isotope which decays moderately slowly so that dispersal would only be possible after an unreasonably long storage period (hundreds of years). These two isotopes are finding increasing use in industry and medicine.—J. Cockcroft, Biological Effects of Nuclear Explosions, *Pharmaceutical Journal*, May 14, 1955.

INVASIVE CARCINOMA OF THE CERVIX IN YOUNG WOMEN

David G. Decker, M.D., Robert E. Fricke, M.D.
and
Joseph Hyde Pratt, M.D., Rochester, Minn.

Invasive carcinoma of the uterine cervix in young women presents a problem that has certain facets of diagnosis and selection of treatment not associated with the condition in the older age groups. The clinical impression of increased virulence of the condition in the younger age group is widespread; yet at the same time, the physician is often less "cancer-suspicious" in evaluating the gynecologic complaints of young women than of older women. Since carcinoma of the cervix is a relatively uncommon condition in young women, the treatment has not always been as standardized as in the older age group. Undoubtedly, in some instances, treatment has been curtailed because of the emotional reaction of the physician and patient to the after-effects of a radiation or surgical menopause in a young woman.

There is also a probability that with more adequate and widespread screening techniques, the incidence of diagnosis of carcinoma in situ will continue to increase. Unfortunately, these techniques are not often applied to girls in their teens, so that the relative incidence of invasive carcinoma of the cervix in the younger age group will increase as the incidence of invasive carcinoma of the cervix in the older age group may decrease. For these reasons it was felt to be worthwhile to review this group of cases of invasive carcinoma of the cervix in young women. A total of 1,451 patients with carcinoma of the cervix were seen at the Mayo Clinic from Jan. 1, 1940, through Dec. 31, 1949. Of these, 169 (11.6%) were 35 years of age or younger and had invasive carcinoma. Limitation of the group at age 35 years was made because (1) the normal reproductive processes in women show little tendency to wane prior to this age and (2) the incidence of invasive carcinoma tends to rise rather precipitately after this age, so that the average age of patients with invasive carcinoma of the cervix is about 49 years.[1]

TABLE 1.—*Age Distribution of Young Women with Invasive Carcinoma of the Cervix*

	No. of Cases, by Age, Yr.		
	20-25	26-30	31-35
Squamous cell epithelioma			
Stage 1	2	6	14
Stage 2	5	7	34
Stage 3	2	7	32
Stage 4	1	1	13
Other malignant lesions	2	3	6
Modified	1	9	24
Total	13	33	123

AGE DISTRIBUTION

The age distribution of the 169 patients is shown in table 1. There is no essential difference in the incidence of early invasive carcinoma (stages 1 and 2) within the age group 26 through 30 years (39.3%) and the age group 31 through 35 years (39.0%). In the age group 20 through 25 years, 53.8% fell in this category, but the group consisted of only 13 cases. There were no patients younger than 20 years in this decade of observation. It is also obvious that by age 31 years, the incidence of invasive carcinoma is rising rapidly.

SYMPTOMATOLOGY

The tabulation shows the primary symptoms of this group of patients. The most prominent symptom by far is intermenstrual bleeding, either traumatic (postcoital) or nontraumatic. Minor abnormalities in menstruation comprise a significant group, as does leukorrhea. As is well known, all of these symptoms are not infrequent in young women, and many of the histories showed a tragic delay on the part of the physician when these symptoms were treated with douches, suppositories, hormones, and cautery prior to a diagnosis by means of a thorough pelvic examination and evaluation of the cervix by cytological smear and biopsy. In only eight cases did diagnosis occur as the result of a complete routine physical examination. All of these were classified as stage 1, and the patients have survived five years. Admittedly, many of the patients tended to minimize their symptoms. The group in which pain was the primary complaint was composed, almost without exception, of the far-advanced cases in which there were also bleeding and a foul leukorrhea.

Primary Symptoms	No. of Cases
Leukorrhea	30
Intermenstrual bleeding	91
Menometrorrhagia	14
Menorrhagia	2
Irregular menses	7
Pain	17
Routine examination (no symptoms)	8
Total	169

The recent emphasis on marital and childbirth trauma as a factor in the etiology of carcinoma of the cervix is not too well substantiated by this group of cases.[2] The tabulation given below shows that a large number of patients, 34 (20.1%) of 169 patients, had never been pregnant. Of the remainder, 135 patients, all had had one or more pregnancies, the greatest number being a total of seven. The tabulation shows the number of marriages per patient. Sixteen of the 169 patients had mul-

at the clinic for additional treatment, and one of these survived more than five years. The relative survival rate of the entire group was 53.5%.

SUMMARY AND CONCLUSIONS

In 169 cases of invasive carcinoma it is apparent that there has been no essential difference noted in the end-results of treatment between the women under the age of 35 years and those over the age of 35 years.[5] A relative five year survival rate of 53.5% was obtained. There was no special predilection noted for more anaplastic tumors in the younger age group under consideration. This is in agreement with the observations of Kahanpää [6] and of Lindell.[7] As many authors have indicated, there is a grievous delay in diagnosis on the part of the physician through misinterpretation of relatively minor symptoms. This is the area in which it would seem the greatest advance could be made. Nothing can replace an adequate pelvic examination, visualization of the cervix and proper cervical biopsy in the armamentarium of the gynecologist. Nor, once the diagnosis has been made, should there be any hesitation to pursue complete tre ment of the lesion because of the age of the patient a the effect of a surgical or radiation menopause. It our impression from this study that carcinoma of t cervix in young women is as malignant as in the over-age group but no more so. For reasons previously stat *the role of surgery is considered to be somewhat grea in the early stages of invasive carcinoma of the cervix young women than in the older age group.* Howev the same patients who are amenable to surgery yi excellent results when treated by irradiation therap so that it is difficult to assess this phase of the proble It is not possible to evaluate the question statistica from this group of cases, and it must remain an individ problem for each patient under consideration. The tin honored precepts of early diagnosis, adequate treatme and careful post-treatment follow-up are nowhere m necessary than in the younger age group.

RADIATION DANGERS IN DIAGNOSTIC RADIOLOGY

Israel E. Kirsh, M.D., Hines, Ill.

Recently there have been warnings of the danger to the population as a whole resulting from the increased use of radioactive materials and of x-ray in diagnosis. However, physicians in general are not yet well enough informed as to the potential harm. In the words of the Handbook on X-ray Protection of the National Bureau Standards,[1] "with the increasing use of radiation and terials emitting radiation, it is necessary for the medical profession to exercise great caution and restraint in the use of X-rays for diagnosis and treatment of non-malignant disease. Current methods and practices should be reviewed to see whether the same result could be obtained with less radiation."

To illustrate the extensive use of ionizing radiation in the United States, it was recently stated by Moeller and associates [2] of the U. S. Public Health Service that there are 126,000 x-ray units for diagnosis and therapy in this country—50,000 used by physicians and hospitals, 65,000 by dentists, and 11,000 by osteopaths and chiropractors. In industry, there are 2,000 radiographic units. Some 30,000 salespeople use fluoroscopes in shoe-fitting, and the number of customers who receive some radiation in this way can only be guessed at. Radium can be bought on the open market by individuals unacquainted with its dangers. It is used in the manufacture of thickness gauges and static eliminators. In research activities, radiation is emitted in the use of cyclotro linear accelerators, electron microscopes, and x-ray d fraction apparatus. In addition, radioisotopes are d tributed by the Atomic Energy Commission to ma medical centers, which have to protect the operating p sonnel and safely dispose of the wastes. To these ty of occupational exposure may be added uranium mini and milling. In addition to this incomplete list is an u avoidable source—cosmic radiation—to which the h man race has always been exposed. It has been es mated [2] that an individual receives up to 9 r from t latter source in a lifetime of 70 years.

In thinking of radiation damage, there has traditio ally been a concern over the danger to radiologis and x-ray technicians, and attention has been conce trated on rather gross, easily recognizable condition such as leukemia, the incidence of which in physicia is twice as high as in the population as a whole and radiologists nine times as high (March [3] and Hensha and Hawkins [4]). In the skin, the type of damage thoug of is radiation-induced carcinoma, which has afflict some pioneer radiologists in their declining years as a r sult of early fluoroscopy without safeguards. Gonad injury has been thought of in terms of sterility or ear interruption of pregnancy. The purpose of this paper i to stress the harm that may result from small doses o radiation, delivered incidentally to fluoroscopy an radiographs made for diagnosis. These doses have bee frequently ignored, even by some radiologists, as bein of no consequence. The reason for this is that the effect are not visible. Relatively small doses of radiation hav a cumulative effect on the germ plasm and cause an in creased rate of mutations. These are generally harmfu genetically.

From the Department of Radiology, Veterans Administration Hospital.

Mr. Wallace Bergeron, Chief Technician, X-Ray Therapy Department, Veterans Administration Hospital, Hines, Ill., made the radiation output measurements.

[4] Henshaw and Hawkins, cited by Stone.[3]

That this danger appears to many in the medical profession to be exaggerated is due to an inadequate appreciation of the implications of H. J. Muller's work on the Drosophila larva. This Nobel-prize-winning research[5] proved that even very small doses of x-ray had a harmful genetic effect, by increasing the mutation rate. In a recent symposium[6] on radiological safety, Muller said that if a total (cumulative) dose of 80 r were given to the gonads before conception, the spontaneous rate of mutations in persons would be doubled; and a doubled rate of mutations for the population as a whole would be harmful to the germ plasm, if it went on generation after generation. It may be said, parenthetically, that a healthy germ plasm, of which this generation is the present custodian, is our most precious resource, one that we have a responsibility to pass on undamaged. Provisionally, Muller says, a total gonadal dose of 20 r (which would produce a 25% increase in the mutation rate) should be considered as approaching the danger level for the species. It is stressed, in Muller's review,[6] that this dosage is a per capita average ceiling, dangerous for the species to exceed. Some individuals could receive much more (risking somatic damage or sterility), if the others had a low enough dose to keep the average down to 20 r. It is sometimes asked whether experimental results with fruit flies are applicable to man. Russell[7] recently approached an answer to this question, by showing in extensive experiments in mice that radiation produced mutations in them 5 to 10 times as often as in Drosophila. It may be, therefore, that our estimate of induced mutations in man, based on Drosophila results, are too low, rather than too high. Meanwhile, prudence calls for action on the existing data obtained from lower forms.

* Output measured on anterior surface of scrotum.

That unduly large amounts of radiation have frequently resulted from diagnostic procedures was shown by Bell.[8] On testing his fluoroscope, as used clinically, the output varied from 25 to 40 r per minute. In individual fluoroscopic examinations of the chest, the output varied from 33 to 134 r per fluoroscopy. In fluoroscopy of the gastrointestinal tract, 148 to 396 r were the actual measured doses in single examinations (some of these lasted as long as 12 minutes). With a new machine, and increased tube-table distance, his x-ray output was reduced by one-half. More recently, Sonnenblick[9] studied 117 fluoroscopes used mainly by pediatricians. Their output, as used by the physicians, varied from 2 to 118 r per minute, with 20% of them exceeding 30 r per minute. All the physicians he questioned were ignorant of the x-ray output of their machines. At Hines Hospital, over a period of five years, measurements have been made of the radiation output of the fluoroscopes and the radiographic machines under clinical conditions. The Victoreen r-meter, an ionization chamber commonly used in checking x-ray therapy machines, was employed.

Average	16.7	24.0	5.9

MEASUREMENTS

In this place, I shall consider mainly the radiographic examinations that, by their location, are most likely to affect the gonads. These are the lumbosacral spine and the urinary tract. The measurements originally made, several years ago, on a patient who had a lumbosacral spine x-ray and a pyelogram are shown in table 1. These measurements were made by placing the Victoreen r-meter in the center of the x-ray beam, on the surface of the skin nearest the x-ray tube. (At that time no added filter was used.) The radiographic factors are omitted here. Slight differences in output were seen in different patients because of variations in exposure factors.

In an initial effort to reduce the amount of radiation in diagnostic x-ray work, a filter that consisted of 1 mm. Al was added to the x-ray tube. Later, another 1 mm. Al was added in order to make a total of 2 mm., and the measurements were repeated (table 1). The fluoroscopes were then measured as to output. The dose (in air) was obtained by placing the r-meter on the fluoroscopic table for one minute, in the position where the patient's back usually is. Results originally obtained (table 3) show the differing outputs in different machines, using the same number of kilovolts and milliamperes. The effect of adding different amounts of filtration in one fluoroscope is seen in the tabulation. As a result of such surveys as these, filtration of 3 mm. Al was added to each of the fluoroscopes in the x-ray department-

ment, as well as those in use on the medical and surgical wards. Filtration of 2 mm. Al was added to each radiographic machine, including the mobile units.

Another possible approach to the problem of protecting the gonads in radiographic examinations is to place a protective covering over them. Magnusson[10] described a hinged metallic cup made to enclose the scrotum, for use when neighboring parts are x-rayed. A simpler expedient, which I have used, is to place a strip of lead-rubber composition over the pubic region. The lead-rubber is available in all x-ray departments, being used for outlining portals in x-ray therapy, and it has a protective value that is equal to 1.5 mm. Pb. It is flexible and can easily be cut to a convenient size. It can be sewed in a compression-band that will remain in place even when the table is made upright. When a pyelogram and a lumbar spine x-ray were made with the r-meter placed over the scrotum and under the lead-rubber strip, no reading was obtained on the large-scale ionization chamber (less than 0.1 r) each time. The measurements obtained in certain types of examinations, under the present conditions, with full added filtration, are given in table 4. These are obtained on the skin in the center of the x-ray beam.

COMMENT

Physicians must remember that there is a specific type of radiation hazard—that of damage to the patient's gonads resulting from the doses received in diagnostic x-ray procedures. This is sometimes ignored because the effects are not visible during the physician's lifetime. Therefore, those who may suffer as a result are the descendents of his patients, possibly several generations removed. These people, bearing radiation-induced defects, will of course be unaware of the cause of their troubles, nor would it do them any good if they did know. However, physicians have a responsibility to try to prevent this problem, as well as those lethal chromosomal mutations, the result of which is an interrupted pregnancy rather than a congenitally deformed individual. In view of these considerations, the results obtained by the use of ionization chambers during radiography are of importance. In some cases there are repeated roentgen examinations of the urinary tract, lumbar spine, gastrointestinal tract, hip, and pelvis, and there is danger of gonadal injury. To think of gonad injury only in terms of sterility is an error shared by n a few physicians.

What measures are available for controlling the da ger discussed here? First, measures to decrease the r diation received by the patient, and especially his gonad in necessary x-ray diagnostic procedures. Second, elin nation of procedures that involve radiation, when po sible. To decrease the radiation received by the patier a simple, inexpensive method is at hand. It is the inse tion of adequate filtration in fluoroscopes and x-ray m chines. A filter that consists of 3 mm. Al is effecti for fluoroscopes. This will reduce the radiation about a quarter of that obtained when no filter is use Another simple measure is careful regulation of t fluoroscope to the lowest setting that will serve. Prop accommodation of the eyes before beginning fluorosco permits a lower setting than would be used without th The fluoroscope should be set at 3 ma., as higher cu rents add nothing except radiation. Russell Morgan advocates certain safeguards in addition to filters. I favors the use of an attachment that shuts off the curre (until it is reset) when the fluoroscope has been us for five minutes. He also stresses the value of restricti the fluoroscopic beam to less than 8 by 10 in., in ord to limit both the direct and the scattered radiation.

In radiography, Trout and his colleagues[12] show that a filter of 2 mm. Al reduces the dose of radiation 80% at 50 kv. and reduces it by 70% at 100 k (most of the radiographic work at this hospital is at vo ages within this range). Tables 1 and 2 show the ve substantial decrease in output obtained at Hines Ho pital when a filter consisting of 2 mm. Al was inserted all the radiographic machines about five years ago. It interesting to note that no adjustment of the x-ray tec nical factors is necessary when the filter is inserted, it absorbs radiation that would not affect the x-ray fil in any helpful way.

Another simple measure that can be used is the pla ing of a lead-rubber strip over the pubic region wh nearby parts are being x-rayed. This is applicable on to male patients, of course. To mask the ovaries wi lead would interfere with the visualization of part of t pelvis and urinary tract on the film. There is also an a ministrative aspect to its use. This device would have be used consistently, for its omission might be inte preted by the patient as the oversight of a necessary pr tection.

The avoidance of unnecessary procedures that i volve radiation is a matter that concerns primarily th physician who is not a radiologist. He is in a key positio in making the decision of whether to obtain an x-ray Radiologists who are asked to make an x-ray examina tion are understandably reluctant to decline on th ground of possible excessive radiation if the referrin physician deems the x-rays necessary. Practitioner generally should understand the hazards. They shoul stop and ask themselves whether there is any other wa of reaching a diagnosis and whether the prospective gai from the examination warrants the risk. Radiation therapy is often recommended not only for malignant disease

but also for benign conditions. The physician should seriously consider, when a benign disease is present, whether some other therapy besides x-ray or radioactive substance is not available and equally effective.

SUMMARY

The geneticist's concept of "maximum permissible exposure" should alert us to the long-range danger for individuals and the population as a whole from relatively small doses of radiation resulting from fluoroscopy and radiography. Many fluoroscopes and radiographic machines are used by medical personnel who are completely unaware of their radiation output. Measurement of output is easily done. The simple measure of inserting aluminum filters in the radiographic and fluoroscopic tubeholder (2 mm. for the former, 3 mm. for the latter) reduces the radiation considerably, without affecting the film or the brightness of the screen. Radiologists and other physicians should think about possible danger to the patient from too many radiographic examinations. Alternatives to radiation therapy should be considered, especially in benign conditions.

DIAGNOSIS OF INFRAPULMONARY PLEURAL EFFUSION

John W. Wilson, M.D., Dallas, Texas

Discussion of infrapulmonary pleural effusion can be found in radiological literature and literature on the chest but has been completely omitted in general medical publications. Consequently, this peculiar type of pleural fluid collection frequently exists unrecognized or misdiagnosed, for it produces the illusion of an elevated diaphragm. It is, of course, necessary to distinguish pleural effusion from diaphragmatic elevation, because the underlying causes of the two abnormalities, which may be entirely different, must be determined before proper therapeutic measures can be undertaken. The differentiation may not be made by diagnostic thoracentesis, for liquid in the infrapulmonary space may not be accessible to the aspirating needle by the ordinary tapping procedure. The diagnosis can be established specifically by simple roentgenographic methods, but these procedures are not performed routinely; before appropriate roentgen examinations are recommended, infrapulmonary effusion must be suspected. It is necessary therefore that all doctors who have the opportunity to observe chest roentgenograms be aware of this entity, suspicious of its existence, and acquainted with the methods and criteria of establishing a precise diagnosis.

Infrapulmonary effusion may be defined as the collection of any liquid or fluid in the pleural space beneath the lung and above the diaphragm. In a review of the literature,[1] only 62 reported cases of subpulmonic effusions resembling an elevated diaphragm were found. Infrapulmonary effusion has been described as "atypical," "uncommon," and "rare." In my experience, it is atypical only in the sense that the accepted roentgen features of pleural effusion are absent: It is neither rare nor uncommon and is, indeed, encountered frequently. Perhaps the incidence of infrapulmonary effusion that I have observed is partially related to the numerous cases of traumatic hemothorax seen in this hospital, for blood in the pleural cavity appears to have a particular propensity toward subpulmonic collections; however, all varieties of liquid, including blood, chyle, serous effusions, pus, and other forms of transudates and exudates, have been observed as infrapulmonary effusions. It becomes apparent that the accumulation of an effusion in the supradiaphragmatic pleural space is largely independent of the composition of the fluid. Korol and Scott[2] have shown that subpulmonic liquid may be capped by a "veiled air bubble"; however, this gaseous capping is not a necessary, or even a frequent, component of infrapulmonary effusion.

Twenty-four cases, obtained from the index files of the department of radiology for an eight month period in 1954, were reviewed for the preparation of this paper. These cases were selected with some discrimination, and several other cases in which there was infrapulmonary effusion in association with the obvious features of pleural effusion were eliminated. More examples of this entity were given routine interpretations and not indexed and are thus lost to further study. Consequently, these 24 patients are not intended to represent the actual incidence of infrapulmonary pleural effusion, for this abnormality is seen with even greater regularity than the number of cases reviewed would indicate. The underlying disease process in these 24 cases was as follows: pulmonary infarction, 2 cases; trauma (hemothorax), 6 cases; acute rheumatic heart disease, 2 cases; Hodgkin's disease, 2 cases; empyema (with subphrenic abscess), one case; basilar pleurisy (complicating acute perforation of duodenal ulcer), one case; breast carcinoma with pleural metastases, one case; bronchogenic carcinoma, one case; chronic glomerulonephritis (nephrotic stage), one case; arteriosclerotic and/or hypertensive heart disease with failure, 5 cases; sicklemia in crisis, one case; and dissecting aneurysm of the aorta, one case. No attempt is

made in this paper to present the films for each case, for they are, in many respects, repetitious. Only those films that illustrate variations of diagnostic importance are presented.

ETIOLOGY AND MECHANISM

Accumulations of effusions in the supradiaphragmatic pleural space may be manifestations of any disease process that results in transudation, exudation, or hemorrhage into the pleural cavity; however, the mechanism of the confinement of effusions in the subpulmonic space is not known. Certainly, loculation is not a feasible explanation, for fluid in the infrapulmonary pleural space may move freely throughout the pleural cavity. Also, confinement of effusions is seen in acute cases (traumatic hemothorax) in which there is no antecedent history or evidence of pleural adhesions and where loculations cannot be presumed. Many factors have been proposed to explain the collection of fluid beneath the lung. Most of the factors that influence the distribution of pleural effusions have been described originally by Rigler[1g] and Hessen,[1c] and it is unnecessary to repeat their discussions. Aside from the factors listed by these authorities, however, it would appear to me that there are two basic principles in the mechanism of infrapulmonary fluid collection. It is reasonable to suggest that the base of the lung is inherently more elastic than the remaining portions and is therefore more mobile. This is illustrated by the commonly recognized fact that a restriction of the lung base produces considerably more encroachment upon the vital capacity than do restrictions in the upper portions of the lung. The relatively small impairment of pulmonary function that results from thoracoplasty is an illustration of this. Furthermore, thoracic surgeons recommend maintaining a patient in the Trendelenburg position in cases of pleurisy or hemothorax, so that any pleural scarring that results will form over the apex rather than the base and a better functional result will be obtained. Another clinical impression that would support the theory of greater mobility of the base of the lung may be derived from the experience encountered with the patients whose cases were reviewed for this paper. Several of the patients who had, solely and entirely, infrapulmonary fluid collections demonstrated a diminished vital capacity and shortness of breath that were relieved with thoracentesis. In one patient, the amount of liquid was only 700 cc., but the respiratory function was completely restored to normal after aspiration of this relatively small volume from the infrapulmonary space.

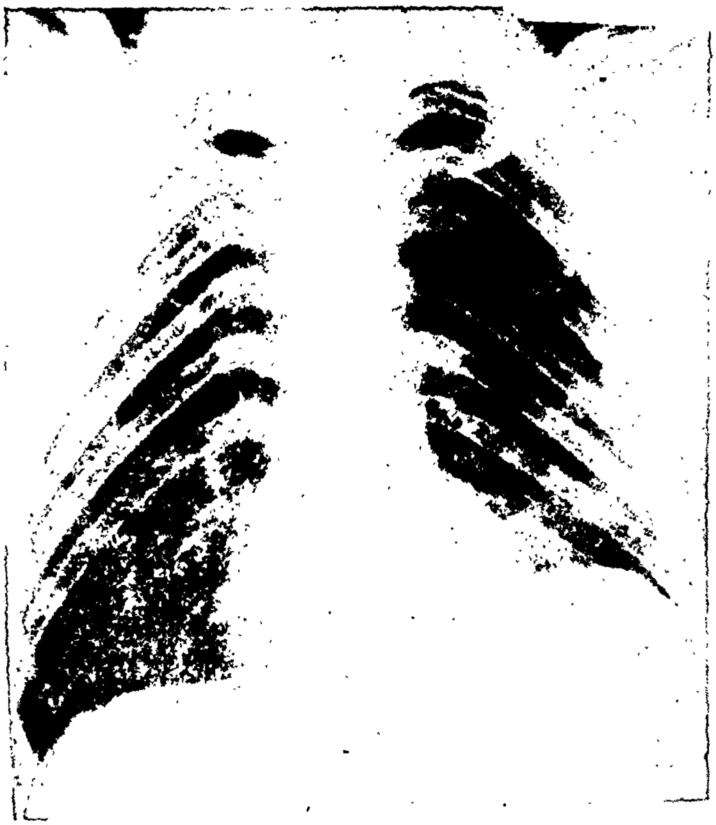

Fig. 1.—Typical infrapulmonary effusion on left resembling hemidiaphragmatic elevation. Note absence of usual signs of pleural effusion. Diagnosis was confirmed by multipositioned roentgenograms, similar to those shown in figure 6.

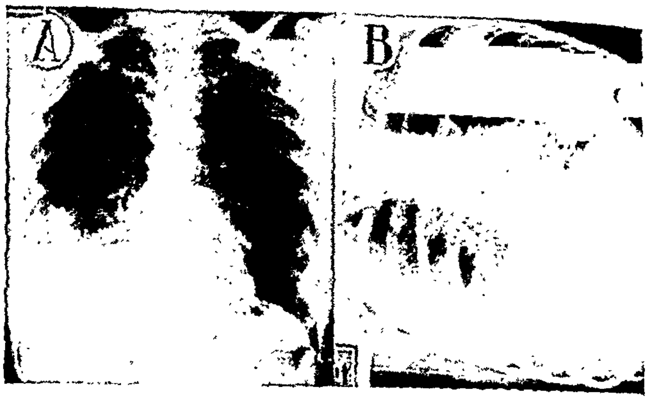

Fig. 2.—*A*, typical infrapulmonary effusion on right resembling diaphragmatic elevation. Note absence of usual signs of pleural effusion. *B*, chest film taken with patient in right lateral decubitus position shows obvious pleural effusion evacuated from infrapulmonary space and now occupying dependent position along lateral chest wall.

A second factor in the mechanism of subpulmonic effusion would seem apparent; that is, that the negative intrapleural pressure would be greatest at the base as a result of diaphragmatic movement. As the diaphragm descends, the negative intrathoracic pressure in the infrapulmonary pleural space is enhanced, so that the existing fluid in the pleural cavity is withdrawn, by virtue of the greater pressure gradient, from the other compartments of the pleural sac that are not influenced so directly by the diaphragmatic excursion. There results a tendency for the fluid or liquid to be sucked into the infrapulmonary space. Conversely, with elevation of the diaphragm, the negative intrathoracic pressure at the base is reduced, or becomes positive, disproportionate to the pressure changes effected in the remainder of the pleural cavity, and the liquid evacuates the subpulmonic space. This phenomenon may be observed in infrapulmonary effusion by having the patient affect forced expiration, the fluid being expressed from the subpulmonic space. With inspiration, the liquid is recovered in the pleural compartment below the inferior surface of the lung.

Briefly, the distribution of fluid in the pleural cavity is dependent upon the competitive forces of the lung and fluid to occupy space; the combined factors of a greater negative intrathoracic pressure in the space above the diaphragm and the greater elasticity of the base of the lung result in fluid collecting in the subpulmonic area. Gravitational force is undoubtedly an important influence, for the diagnosis is resolved by observing the fluid migration to dependent portions, when the patient is placed in various positions.

RECOGNITION AND DIAGNOSIS

The recognition of this entity is directly proportional to the interpreter's suspicion and his subjection of the patient to proper roentgenographic procedures. It is recommended that any patient who shows clinical or roentgenographic signs simulating an elevated diaphragm should have further studies to exclude the presence of infrapulmonary effusion. It has been shown by other investigators[3] that pleural liquid may not be recognized roentgenographically in quantities less than 400 cc. Possibly the reason that effusions of this magnitude and less cannot be detected by the routine anteroposterior chest roentgenogram, made with the patient in the upright position, is that the liquid collects in the subpulmonic space and, when distributed over the diaphragmatic dome, is not apparent even as infrapulmonary effusion. Consistent with this assumption is the theory that infrapulmonary effusion represents the earliest stages of fluid collected in the pleural cavity.[1b] The usual signs of pleural effusion superseding the signs of infrapulmonary effusion have been observed in several instances after progressively larger quantities of liquid collect in the pleural cavity; however, fluid, in volumes exceeding 1,000 cc., may locate exclusively in the subpulmonic space without producing any of the accepted roentgen features of pleural effusion. Therefore, infrapulmonary collections do not necessarily carry the inference that the effusion is either early or small in amount.

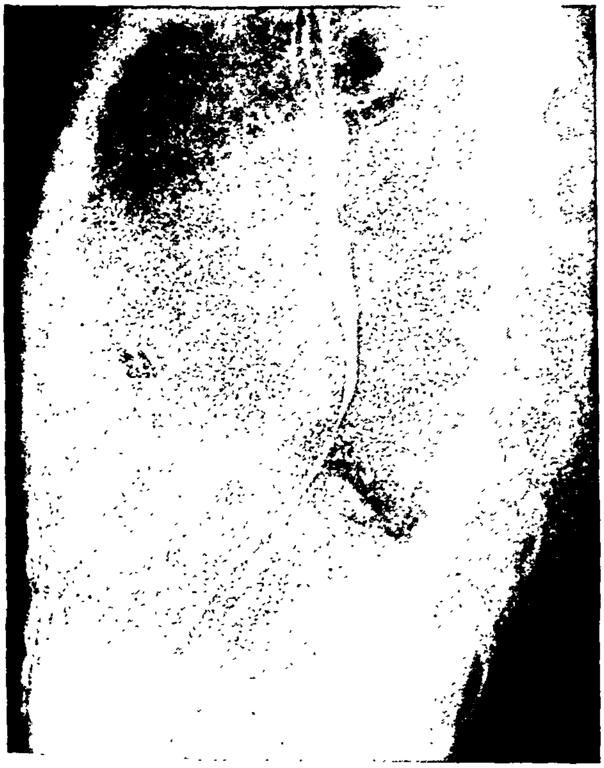

Fig. 3.—Lateral view of infrapulmonary effusion on right simulating elevated diaphragm. Superior limits of infrapulmonary effusion on right resemble normal diaphragmatic contour. Posteroinferior slope and sharpness of posterior costophrenic sulcus are preserved. Small linear density (arrow) in major lobar fissure inferiorly is only clue that effusion may exist.

Distribution of Effusion.—On the routine anteroposterior chest roentgenogram, made with the patient in the upright position, the density of the liquid in the subpulmonic space forms an arcuate convexity on its superior surface and blends with the diaphragmatic shadow below to resemble an elevated diaphragm (fig. 1, 2*A*, 3, 4, 5, and 6*A*). The superior convex border of the liquid, as delineated by the visceral layer of the pleura on the undersurface of the lung, is sharp, round, and smooth and may conform identically to the usual arcuation of the diaphragmatic leaf. On the lateral chest roentgenogram (fig. 3), the normal caudal slope of the diaphragm posteriorly is maintained and the posterior costophrenic sinus may remain sharp, although, ordinarily, filling of the posterior pleural sinus is considered the earliest sign of pleural effusion. Other common diagnostic roentgen features of pleural effusion, such as blunting of the costophrenic sinuses, flattening of the diaphragmatic shadow, blurring at the lung base, graduating zones of opacity,[4] the ribbon-like density along the lateral thoracic wall,[5] and dislocation of the mediastinal contents toward the opposing slide, may also be completely absent. Occasionally, the diagnosis can be inferred from the contour of what appears to be the diaphragmatic dome. The superior border of the fluid originating medially may course obliquely upward toward the lateral thoracic wall and extend farther laterally than the normal diaphragmatic cupula, before it descends into the lateral costophrenic sinus (fig. 4). This contour is not precisely that of the normal diaphragm, and when it is observed infrapulmonary effusion may be suspected.[1c] Of course, if any of the usual roentgen features of pleural effusion are present in association with what appears to be an elevated diaphragm, a subpulmonic fluid collection should be suspected. At times, a small amount of liquid may be seen dissecting into the inferior portion of the major

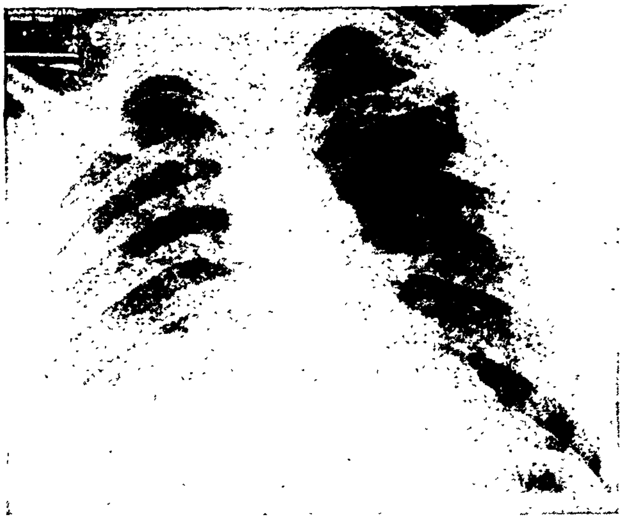

Fig. 4.—Infrapulmonary effusion simulating elevation of right hemidiaphragm. Note angulation and lateral descent of superior margin of effusion, which differs slightly from normal contour of diaphragmatic leaf.

lobar fissure (*fig.* 3), which may be a clue that pleural effusion actually accounts for the apparitional diaphragmatic elevation. If the infrapulmonary fluid collection is on the left, its presence may be suspected by the increased distance between the inferior margin of the lung and the superior margin of the gastric air bubble (fig. 5*A* and 6*A*). Normally, the gastric fundus occupies an anatomic position directly under and in close proximity to the diaphragm; any increased thickness of the density between these two structures may be interpreted as an interposed mass or fluid situated subdiaphragmatically or supradiaphragmatically. In such a circumstance, it is advisable to do barium studies of the stomach [6] or distend the stomach with gas by giving the patient a carbonated beverage or compound effervescent powder (Siedlitz powder). If, by these studies, the gastric fundus is shown to remain smooth and round and maintain its normal contour, one may exclude the possibility that the fluid is collected beneath the diaphragm, for, in this instance, it would impress or otherwise deform the gastric outline. With this line of reasoning, one may conclude that the distance between the base of the lung and the smooth, round gastric fundus is produced by a collection of fluid above the diaphragm in the pleural cavity. In infrapulmonary effusions of the right side, a similar diagnostic sign would have to be obtained by the presence of free air in the peritoneal cavity (pneumoperitoneum, diagnostic or spontaneous) serving as a contrast medium to outline the undersurface of the diaphragm. Any accentuation of the thickness of the space between the abdominal air and the lung base may be interpreted as an interposition of fluid in the infrapulmonary space (fig. 5*B*).

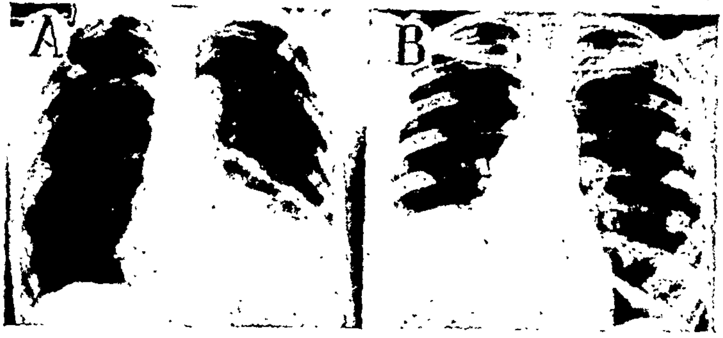

Fig. 5.—*A*, infrapulmonary effusion on left indicated by accentuated distance between the superior limits of gas-distended gastric fundus (patient was given a carbonated beverage) and inferior limit of left lung. Fundus is not deformed, indicating that interposed density is above diaphragm. *B*, infrapulmonary effusion on right complicating large subphrenic abscess. *Gas-filled cavity delineates undersurface of diaphragm*, indicating that supradiaphragmatic pleural effusion is responsible for increased thickness of density between diaphragm and lung base. Same sign may be elicited by diagnostic pneumoperitoneum.

Change in Distribution.—Ordinary anteroposterior chest roentgenograms, taken with the patient in the upright position, exposed during the expiratory phase, illustrate another feature of diagnostic consequence; that is, that the distribution of the effusion may be changed. When the roentgenogram is exposed during this phase, the liquid is forcibly displaced from the infrapulmonary space by the ascent of the diaphragm and assumes the typical S-line of pleural effusion. This may also be observed by fluoroscopy.[1a] Parsonnet [1f] effected a similar change by pneumoperitoneum in which the intraperitoneal pressure produced elevation of the diaphragm and displaced the fluid from beneath the lung.

At roentgenoscopy, the superior convex contour of the fluid may show an excursion consistent with the normal diaphragmatic movement, but, with closer observation, one sees transmission of the cardiac pulsations through the liquid medium. Six of the patients whose cases were reviewed for this paper and who were observed under the fluoroscope showed a pulsatile activity of the superior margin of the infrapulmonary effusion that was synchronous with the cardiac cycles. If this finding is recognized at fluoroscopy, the diagnosis will be evident.

Shift of Effusion with Different Positions.—Fluoroscopic or roentgenographic examination of the patient in different postures, so that the shift of the effusion from the infrapulmonary space can be observed, is perhaps the easiest and most informative of the roentgen procedures. As the patient is put in the decubitus position (lying on the affected side), the liquid is seen in the lateral costophrenic sinus and along the lateral thoracic wall, producing the characteristic ribbon-like density of pleural effusion (fig. 2*B* and 6*B*). If the patient is put in the opposite decubitus position (lying on the unaffected side), the liquid dissects into the mediastinal reflection of the pleural cavity (fig. 6*C*). With the patient

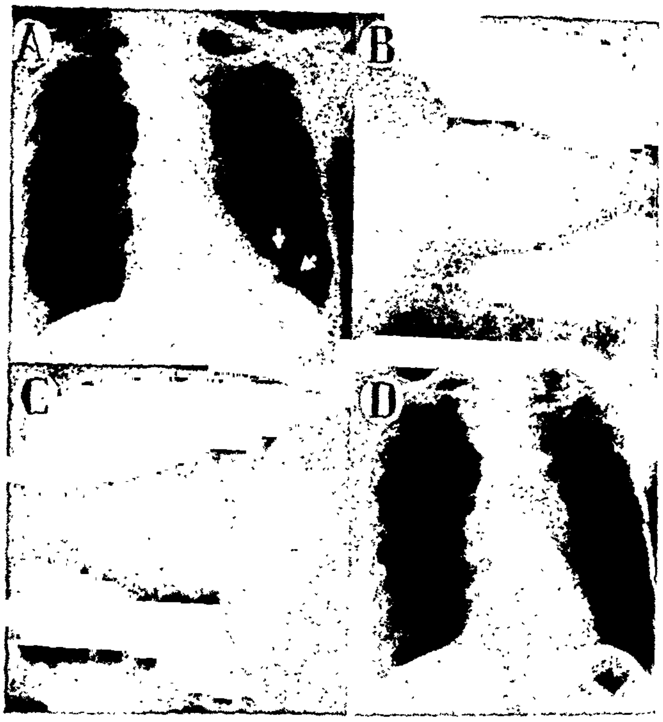

Fig. 6.—*A*, routine anteroposterior chest roentgenogram, taken with patient in upright position. Elevation of left hemidiaphragm and solid parenchymal mass (arrows) in left lung base appear to be present. The patient had had radical mastectomy for breast carcinoma, and mass was initially interpreted as metastatic lung lesion. *B*, anteroposterior chest roentgenogram taken with patient in left lateral decubitus position. Effusion dissects laterally, and apparent lung density has disappeared. *Illusion of diaphragmatic elevation is lost. C*, anteroposterior chest roentgenogram taken with patient in right lateral decubitus position. Effusion occupies mediastinal reflection of pleural cavity, and there is no longer illusion of high left leaf of diaphragm or mass in left lung. *D*, routine anteroposterior chest roentgenogram, taken with patient in upright position (taken after thoracentesis). No fluid could be obtained until patient was placed in left lateral decubitus position, at which time 700 cc. was removed and symptoms were completely relieved. Diaphragm is at normal level, and there is no evidence of residual pleural effusion. Note relative distance between gastric air bubble and inferior margin of left lung. Compare this film with initial film of patient before thoracentesis (fig. 6*A*).

---

6. Hodges, F. J.: Downward Displacement of Gastric Cardia, Radiology 54: 194 (Feb.) 1950.

in the Trendelenburg position, the effusion gravitates over the apex; with the patient in a supine position, the liquid forms a thin sheet in the dependent posterior pleural space and produces a general hazy opacification of the affected hemithorax. With the patient in any of these positions, as the effusion is distributed to dependent portions of the pleural cavity, the illusion of an elevated diaphragm is dispelled (fig. 6*B* and 6*C*). Yater and Rodis[13] observed by fluoroscopy the shift of a pleural effusion when the patient was moved from a recumbent to a vertical position. With vertical tilting, the liquid remained in the posterior pleural space until the patient's position was almost upright. At this instant, the fluid collected in the infrapulmonary space, simulating the original appearance of an elevated diaphragm. This sequence has been duplicated repeatedly in our patients.

Kymography.—Roentgen kymography may be used to observe the pulsatile activity of the infrapulmonary liquid and its movement coincident with the diaphragmatic excursion; however, this is a refined roentgenographic procedure that is not available to most physicians and is not necessary in the diagnosis of infrapulmonary effusion.

Evaluation of Pulmonic Structure.—Comment should be given to an additional diagnostic application of roentgenograms exposed with the patient in different positions when a pleural effusion exists. Frequently, the density of the pleural liquid masks roentgenographic study of the lung, and it is impossible to evaluate the integrity of the pulmonic structures. If films of the chest are exposed with the patient in various postures, corresponding portions of the lungs will be cleared of the superimposed pleural density and hidden pulmonary abnormalities may become evident. Conversely, confusing pleural fluid densities that are interpreted as lung pathology may disappear as the position of the patient is changed. This point is illustrated in figure 6*A* where the apparent nodular density in the left base, which was interpreted initially as a metastatic lung lesion, completely vanished on the multipositioned films. It obviously represented a fortuitous density of the pleural liquid, which produced the visual impression of a solid lung mass. Furthermore, in patients who have passive congestion of the pulmonary venous circuit, the lateral decubitus position will effect a redistribution of the venous stasis to the dependent lung; the lung on the upward side will appear to be free of any congestion, which renders it roentgenographically clear and eliminates the deceptive shadows of vascular engorgement. This phenomenon has been observed on several occasions and made it possible in two cases to perceive a hypostatic pneumonia that was not otherwise an available roentgen diagnosis.

TREATMENT

The treatment of infrapulmonary pleural effusion is not unlike the treatment of pleural fluid of any etiology; however, thoracentesis may be unsuccessful in evacuating the fluid from the infrapulmonary space (legend, fig. 6) unless the patient is placed in a decubitus position with the involved side down during the tapping procedure.

In infrapulmonary effusions, the respiratory incapacity may be quite severe, even though the volumetric accumulation of the fluid is relatively small. The cause for this has been alluded to in the foregoing paragraphs and, in part, may be based upon the greater mobility and elasticity of the lung base, so that any encroachment at this point is more severely reflected in functional deficiencies. Even if the effusion is not quantitatively sufficient to effectively reduce the ventilatory space, difficult breathing may still result from (1) the mechanical presence of the effusion reducing the pulmonary compliance and (2) the proprioceptive reflexes occasioned by the pressure of the fluid on the lung or diaphragm, which tends to perpetuate inspiration and hold the lungs in a state of inflation. With this physiological concept and with the experience encountered with the patients reviewed for this paper, it is recommended that a thoracentesis be performed if there are any symptoms of respiratory embarrassment, even though only small collections of fluid in the infrapulmonary space are present. Any further treatment is the same as the usual therapeutic measures for the underlying disease.

SUMMARY

The incidence of infrapulmonary pleural effusion in my experience is greater than is recognized. An accurate diagnosis of this condition can be established by the use of proper roentgenographic procedures. Two basic factors in the mechanism of confinement of fluid in the infrapulmonary pleural space are the greater negative intrathoracic pressure in the space above the diaphragm and the greater elasticity of the base of the lung. Even though the amount of accumulated fluid may be small, respiratory incapacity may be severe; thoracentesis is recommended if there are any symptoms of respiratory embarrassment.

The Waterhouse-Friderichsen Syndrome.—The seriousness of the Waterhouse-Friderichsen syndrome has been stressed since its original description. The classical picture of an acute infection, usually meningococcemia, associated with profound circulatory collapse and followed rapidly by purpura, anuria, hypoglycemia and death is well known. . . . In the patient whose condition clinically suggests this syndrome, blood morphology may be a valuable diagnostic aid. A marked neutrophilia with normal eosinophil levels, or even eosinophil levels above 50 to 75 per cu. mm. of blood, are common findings. . . . Blood and spinal fluid smears and cultures should be made. This is one of the rare instances in which bacteria, usually meningococci, may be found in a direct blood smear, especially one made by puncturing petechiae in the skin. Smears and cultures of spinal fluid generally are negative, since death usually occurs before the leptomeninges are invaded. . . . Prior to the advent of cortisone, patients developing the Waterhouse-Friderichsen syndrome died. Today, however, a considerable number of patients treated with antibiotics and adrenal steroids recover. Therapy is directed along three lines: (1) intensive antibiotic treatment for control of the infection; (2) cortisone and hydrocortisone in large, repeated doses; and (3) other supportive measures, as adequate fluid and electrolyte replacement.—C. CLINICAL NOTES

CHRONIC PULMONARY BERYLLOSIS

Peter A. Theodos, M.D.
Heinrich Brieger, M.D.
and
Richard T. Cathcart, M.D., Philadelphia

The occurrence of progressive changes in the lungs after exposure to finely divided beryllium compounds is now well recognized.[1] The clinical picture may be acute or chronic and is characterized in both types by pulmonary insufficiency. The chronic form occurs usually after a period of clinical latency following the last exposure to beryllium. The characteristic pathological picture in chronic beryllosis consists of multiple granulomas, increased interalveolar septal fibrosis, and a lymphocytic and mononuclear cellular response. The diagnosis is frequently unsuspected because of the delayed emergence of symptoms after the last contact and the similarity clinically and on the roentgenogram to sarcoid, silicosis, and tuberculosis. The roentgenographic findings may precede symptoms by many years or may not be noted until after the onset of symptoms. The following case is considered of interest because, although it embodies the classical clinical features of the disease, the definitive diagnosis was established and appropriate treatment made possible only through the medium of a lung biopsy.

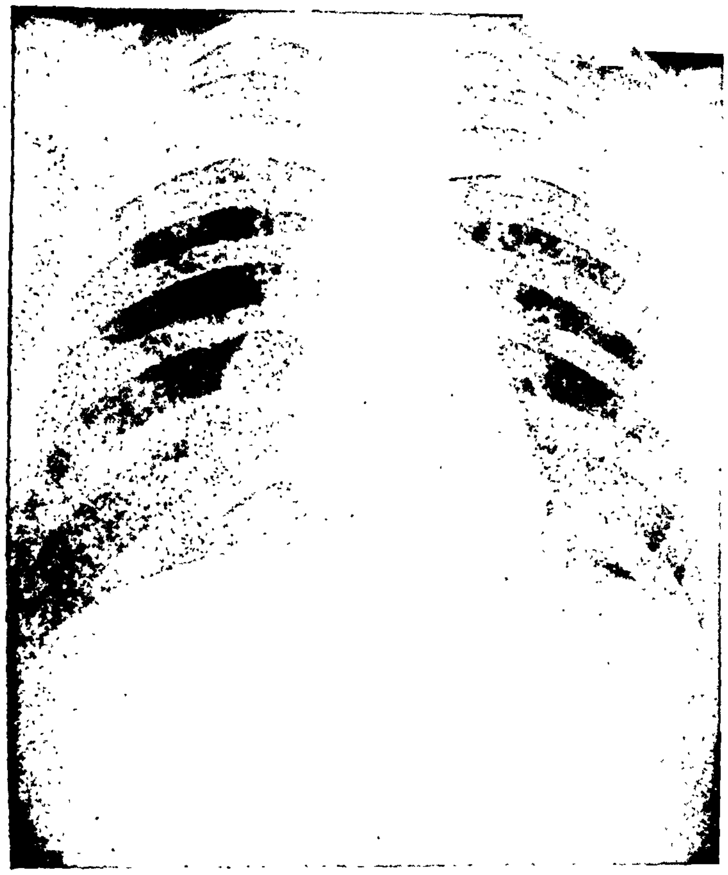

Fig. 1.—Roentgenogram showing diffuse coalescent nodular infiltration, most marked in the upper lobes.

REPORT OF A CASE

A 30-year-old Negro male was admitted to the hospital on June 20, 1953, with the chief complaint of dyspnea for one year. This was previously present on exertion only but was now present even at rest. His only other complaints were a dry cough and a weight loss of 5 lb. (2.3 kg.) in the past six months. Systemic review was essentially normal. The history was significant. For a period of four months between October, 1942, and January, 1943, he had worked in a factory using beryllium. His duties had been to mix chemicals in powder form. He had stopped work because of the development of a generalized rash and swelling of the joints of undetermined cause. He served in the Army from 1944 to 1946, being stationed in the Philippines, Japan, and France. From September, 1946, until the present he has been employed as an attendant in a Veterans Administration hospital. A preemployment roentgenogram on Sept. 9, 1946, revealed some increase in the hilar shadows bilaterally but no parenchymal disease. Subsequent serial roentgenograms showed no change until May 5, 1949, when the right hilar shadows appeared more prominent. Slight granularity of the lung fields was first detected on a roentgenogram of Nov. 29, 1950. By June 11, 1951, definite stage 1 nodulation was present. Hospitalization for 42 days was effected at this time. The only significant finding was the report of sarcoid following a supraclavicular fat pad biopsy. Subsequent roentgenograms showed increase in the nodulation with beginning coalescence in April, 1952. The last film (March 10, 1953) prior to this admission showed further coalescence of the nodules. Physical examination revealed a well-developed and well-nourished adult Negro in no apparent distress. The pulse rate was 88 per minute, blood pressure, 130/80 mm. Hg, weight, 172 lb. (78 kg.), and respirations, 24 per minute. The lungs were clear throughout, and the rest of the general examination revealed no abnormalities. Roentgenographic study (fig. 1) revealed a coalescent nodular infiltration throughout both lungs, most marked in the upper lobes. The lymph nodes in both hilar regions were enlarged. Both leaves of the diaphragm were smooth and showed 80% of normal motion. A complete blood cell count and urinalysis revealed normal findings. The blood protein value was 7.84 gm. per 100 cc., with albumin 5.4 gm. per 100 cc. and globulin 2.7 gm. per 100 cc. The tuberculin test was negative to both strengths of purified protein derivative of tuberculin.

The clinical picture was compatible with pulmonary sarcoidosis or pulmonary beryllosis. For purposes of definitive diagnosis a lung biopsy with the use of the Klassen technique[2] was performed on June 23, 1953, with the patient under local anesthesia. The lung was found free in the pleural space and contained fine nodules throughout the entire palpable area. Histological study revealed the typical pattern of chronic pulmonary granulomatosis seen in beryllosis (fig. 2). Pulmonary function studies gave the following results: vital capacity, 2,982 cc. (55% of predicted value); maximum breathing capacity, 181 liters per minute (127% of predicted value); ventilation at rest, 7.7 liters per minute; ventilation during the first minute of recovery, 40.5 liters per minute; arterial oxygen saturation at rest, 95% and after exercise, 79.8%; and residual volume, 1,297 cc., representing 27% of total lung volume.

From these findings it was evident that no significant emphysema was present and that ventilatory function was excellent despite a restricted lung volume. These features, in addition to the hyperventilation that was very marked on exercise and the precipitous fall in arterial oxygen saturation, strongly suggested

the presence of the syndrome described as "alveolar-capillary block," which is typically seen in beryllosis.[3] After treatment with 1,900 mg. of cortisone over a period of 11 days, objective improvement was noted. The vital capacity had increased to 3,461 cc. and the maximum breathing capacity to 216 liters per minute. The resting arterial oxygen saturation was 98.0% and significantly fell to only 89.6% after exercise. The resting ventilation was of the same order as before treatment, but there was a diminution of the ventilation during the recovery period. Subjective improvement was also noted. The patient's sense of well-being was enhanced, and he performed the exercise with far less discomfort. After the above studies were completed, therapy was started with a maintenance dose of 50 mg. of cortisone daily for the next 30 days. The dose was then reduced to 25 mg. daily, and this dosage was continued until Jan. 12, 1954. Physiological studies at that time revealed no further improvement in the patient's pulmonary function. Repeated roentgenograms of the chest taken during the period of treatment have shown no change in the nature or extent of the pulmonary changes. Symptomatically there has also been no further improvement in the degree of cough or dyspnea.

COMMENT

Pulmonary involvement in beryllosis results from inhalation of finely divided beryllium compounds. The normal protective mechanism of the upper respiratory tract removes a considerable number of the inhaled particles, but a variable number reach the alveoli. Absorption occurs from the lungs, depending on the solubility of the compound, and the beryllium is distributed throughout the body.[1d] It appears that the less soluble compounds tend to cause chronic beryllosis, which may explain the delayed emergence of symptoms after exposure. In this case the exact nature of the inhaled compounds was not determined. The onset of chronic beryllosis may be insidious, with minimal cough and fatigue, but pulmonary insufficiency is soon evidenced by progressive dyspnea and cyanosis. The basic defect in pulmonary function is that of an alveolocapillary block, in that there is impaired diffusion of oxygen across the alveolar membrane, the permeability of the latter presumably having been altered by the deposition of beryllium granulomas. Pulmonary emphysema is generally not present early, and ventilatory function is normal. These facts were exemplified by the pulmonary function studies in this case that indicated the basic defect to be that of an alveolar-capillary disturbance. As the granulomatous process develops, emphysema becomes a factor.[4]

The diagnosis in chronic beryllosis is generally difficult. The delayed emergence of symptoms does not bring the patient to the roentgenologist very early. The roentgenologic picture itself is not specific, and without a history of exposure to beryllium the true diagnosis may not be suspected. It is in such diffuse pulmonary lesions that lung biopsy affords the means of establishing a rapid, accurate diagnosis. The histological findings are sufficiently specific to permit identification if an adequate piece of lung tissue can be obtained for study. This is readily possible by means of the Klassen type of biopsy. The procedure is simple, well tolerated, and produces minimal complications.[5] It has been possible to recover beryllium from the lungs of persons who have died of beryllosis.[6] It remains to be seen whether the small amount of tissue obtained by this form of biopsy will permit this determination.

The prognosis without treatment is generally poor, mortality rates ranging from 10 to 25%. Death occurs from pulmonary insufficiency with eventual failure of the right side of the heart. The use of corticotropin (ACTH) and cortisone has produced definite improvement subjectively and objectively as measured by pulmonary function studies. These agents appear to retard the progression of the disease into a more fibrotic state.[1a] Prompt application of this form of therapy was possible in this case with establishment of the correct diagnosis after biopsy. There was definite improvement with the use of cortisone over a period of six months as reflected in the symptoms and pulmonary function studies; however, no change in the roentgenogram was noted.

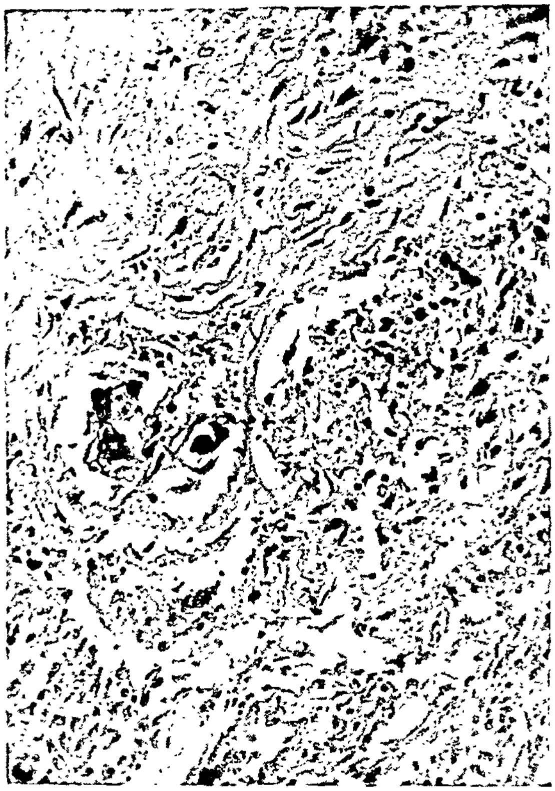

Fig. 2.—Photomicrograph showing a granuloma containing several doubly refractile, blue, laminated, amorphous bodies characteristic of beryllosis, × 200. Note the marked fibrosis.

SUMMARY

In a case of chronic pulmonary beryllosis, with onset of disease eight years after exposure to beryllium had ceased, a definitive diagnosis was established through the medium of a lung biopsy. Treatment with cortisone appears to have produced temporary arrest of the disease.

TREATMENT OF PYELOURETEROCYSTITIS CYSTICA WITH NEOMYCIN

Capt. Robert S. Cox Jr. (MC), U. S. Army
Ward A. Soanes, M.D.
and
Col. Earl C. Lowry (MC), U. S. Army

Pyeloureterocystitis cystica is a progressive disease of obscure etiology, but the concensus of opinion is that it is secondary to chronic urinary tract infection.[1] Numerous treatments have been advocated, but all have apparently given only temporary relief and have not altered the basic progression of the disease. It was our opinion that intensive chemotherapy would eliminate the chronic focal infection and thus stop the progression. The patient whose case is to be presented had a chronic pyelonephritis, due to Aerobacter aerogenes, that was resistant to all of the commonly used antibiotics. After many attempts at chemotherapy had failed, neomycin was given intramuscularly, with dramatic results.

Neomycin was chosen, since A. aerogenes is generally sensitive to this drug and neomycin resistance does not correlate with resistance to other broad-spectrum antibiotics, with the possible exception of streptomycin.[2] Intramuscular administration is necessary, since this drug is poorly absorbed from the gastrointestinal tract. When given parenterally, it is preferentially excreted by the kidneys, thus making it an excellent drug for treating genitourinary tract infections. There is evidence that bacteria rarely develop resistance to neomycin in vivo.[3]

The primary toxic effects of neomycin are damage to the auditory portion of the eighth nerve and to the renal parenchyma. Recent evidence, however, indicates that the therapeutic-toxic ratio is low enough that use of neomycin is indicated if the following criteria are met [4]: (1) a neomycin-sensitive organism is present that does not respond to less potentially toxic agents, (2) renal function is good, and (3) dosage is limited to 1 gm. per day for 8 to 10 days. Waisbren and co-workers,[3a] Nesbit and co-workers,[4a] and Duncan and co-workers [4b] have reported series of genitourinary tract infections treated with parenterally given neomycin. They achieved excellent therapeutic results and no serious toxic side-effects when the above criteria were strictly followed.

REPORT OF A CASE

The patient was a 37-year-old white male, whose history revealed recurrent otitis media in childhood and scarlet fever at age 11. There were no known sequelae and no history indicative of chronic renal disease. In October, 1951, during a routine physical examination, a diagnosis of inactive aortic insufficiency was made. In February, 1952, he had onset of acute chills and fever and was hospitalized. A diagnosis of subacute bacterial endocarditis due to alpha-hemolytic streptococci was made, and he responded well to massive doses of penicillin. In April, 1952, he had an episode of apparently sterile left cerebral embolism, with subsequent nearly complete recovery. In August, 1952, he was digitalized due to extensive cardiac valvulitis and has since been maintained with 0.1 gm. of digitalis daily, with no episodes of cardiac failure. During this hospitalization no evidence of any renal disease was noted. In August, 1952, he developed an abscessed tooth from which alpha-hemolytic streptococci were cultured. This extraction and further dental work was covered with therapeutic courses of penicillin and oxytetracycline (Terramycin).

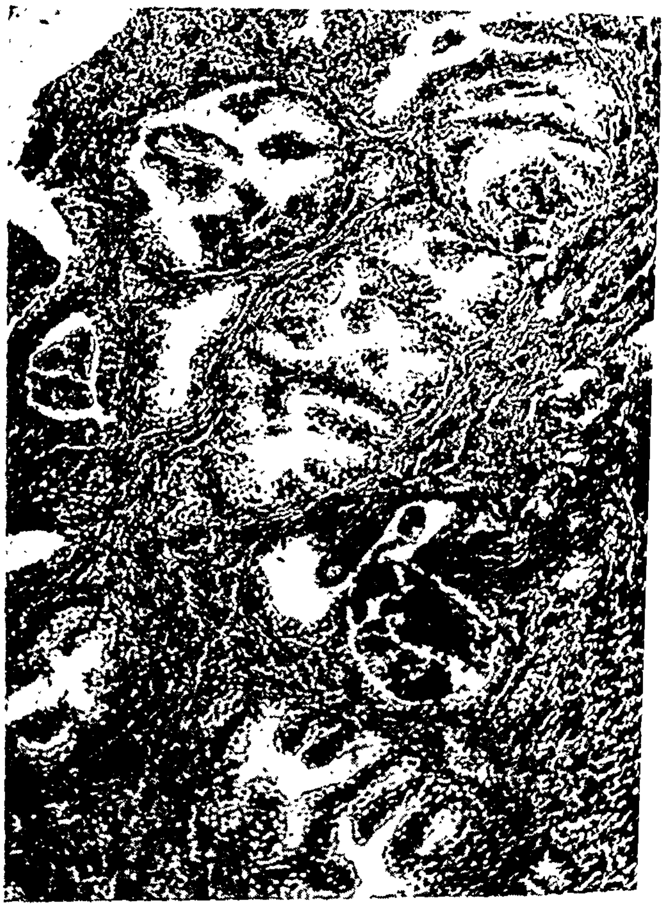

Fig. 1.—Biopsy specimen of bladder lesion showing cystitis glandu cystica (× 100).

On Dec. 1, 1952, the patient was again hospitalized with cl
and fever, sharp left subcostal pain, and urinary frequency
burning. Blood cultures were repeatedly negative, but a g
pyuria was noted from which A. aerogenes was cultured.
organism was sensitive in vitro to chloramphenicol and stre
mycin and resistant to penicillin, bacitracin, chlortetracy
(Aureomycin), and oxytetracycline. No other antibiotics
tested. Urine cultures and guinea pig inoculations for M
bacterium tuberculosis were negative. Intravenous and r
grade pyelograms revealed minimal calycectasis of the mi
calyx of the left kidney, compatible with an old pyelonep
or pyelitis cystica.[1a] Cystoscopy revealed a picture typic
cystitis cystica in the bladder. Biopsy of the cystic lesions
done, and the pathological diagnosis was cystitis glandu
cystica (fig. 1). From December, 1952, through February,
the patient was given massive doses of chloramphenicol
hydrostreptomycin, sulfisoxazole (Gantrisin), and methena
(Mandelamine) mandelate in various combinations, with
erate clinical improvement; but the gross pyuria persisted,

From Letterman Army Hospital, San Francisco. Now at Buffalo (*Dr. Soanes*).

The neomycin used in this study was supplied by the Upjohn Company, Kalamazoo, Mich.

The tube sensitivity tests for this study were done by Dr. Ernest Jawetz, Professor of Microbiology, University of California School of Medicine, San Francisco.

the urine culture remained positive. Repeat in vitro sensitivity tests at this time showed that the Aerobacter organisms had become insensitive to chloramphenicol and streptomycin, but additional tests showed them to be moderately sensitive to sulfisoxazole, neomycin, and polymyxin. Further intensive therapy with penicillin, streptomycin, and sulfisoxazole combined and a therapeutic course of polymyxin did not help. Therapy with polymyxin was stopped after seven days due to neurotoxic symptoms. Repeat cystoscopy and retrograde pyelography in March, 1953, showed marked progression of the cystic lesions into both ureters and the pelves of both kidneys (fig. 2). Urine cultures from both ureters were positive for A. aerogenes. The patient was given further intensive sulfisoxazole therapy and a therapeutic course of nitrofurantoin (Furadantin) with no improvement.

On July 28, 1953, the patient was rehospitalized for a trial of therapy with intramuscularly given neomycin. In vitro tube sensitivity tests on the Aerobacter organisms at this time showed that neomycin was inhibitory and lethal in a concentration of 2 mcg. per milliliter but only inhibitory at 1 mcg. per milliliter. No other single antibiotic was lethal. The only antibiotic combination that was lethal was polymyxin, 0.5 mcg. per milliliter, plus chloramphenicol, 10 mcg. per milliliter. There was no synergism between streptomycin and neomycin. These results were not reported until the initial course of neomycin and streptomycin had been completed. Blood urea nitrogen values were normal, and audiograms with masking revealed a 1 to 3% high tone loss bilaterally. Cystoscopy was performed again with essentially the same findings as before, and sodium indigotin disulfonate and phenolsulfonphthalein dye tests revealed good renal function. Therapy was started with 0.5 gm. of neomycin twice a day and 1 gm. each of streptomycin and dihydrostreptomycin daily. Within 48 hours, there was no microscopic pyuria, urine cultures were sterile, and there were no further urinary symptoms. After a week, therapy with the streptomycins was discontinued and the dosage of neomycin changed to 0.5 gm. daily for one additional week. One-quarter gram was then given twice a week for a month and once a week for another two weeks. During this time no microscopic pyuria was noted and urine cultures were repeatedly sterile. Seventeen days after therapy was stopped the patient had a recurrence of gross pyuria that promptly cleared with a single 0.5 gm. dose of neomycin. In the succeeding 10 months the patient has had six mild recurrences of pyuria with concomitant urine cultures growing A. aerogenes. In each case a single 0.25 gm. dose of neomycin has been completely effective in clearing the pyuria and sterilizing the urine. The Aerobacter organisms have remained moderately sensitive to neomycin in vitro but insensitive to all other antibiotics tested.

In March, 1954, cystoscopy and retrograde pyelograms were repeated and it was felt there had been approximately a 50% reduction in the cystic lesions of the bladder. Blood urea nitrogen values have remained normal, and a repeat audiogram showed a 12 to 15% high tone loss bilaterally. This was felt to be an appreciable, but not clinically significant, hearing loss. The patient is still being followed in June, 1955, and single 0.25 gm. doses of neomycin once or twice monthly are controlling all signs and symptoms.

COMMENT

Neomycin has long been thought of as a toxic drug, but recent literature reviews indicate that it is safe when properly used. In the case presented here, this drug was given in intermittent small doses for two years, after a therapeutic course. There was an excellent therapeutic response, and no serious toxic side-effects were observed. In spite of intensive and varied antibiotic treatment the severe chronic pyelonephritis due to A. aerogenes persisted in this patient until intramuscular therapy with neomycin was instituted. It is felt that the streptomycin played no role in this case, since it showed no synergism in vitro and was previously ineffective. The pyuria disappeared, and the urine culture became negative within 48 hours. The patient has had only infrequent mild recurrences since that time; these have been promptly and completely controlled with a single small dose of neomycin. Cystoscopy and pyelography have revealed a marked regression of the cystic disease since the institution of neomycin therapy, instead of the expected progression. It is postulated that pyeloureterocystitis cystica is a sequela of chronic urinary tract infection and that the patient is continually reinfected by the rupture of the small cysts. If this reinfection is not promptly controlled by effective antibiotic therapy the disease progresses. Many of the organisms producing the chronic urinary infections are resistant to the commonly used antibiotics, and thus treatment has been difficult. Neomycin has been shown to be an effective and safe drug to use in controlling some of these resistant infections.

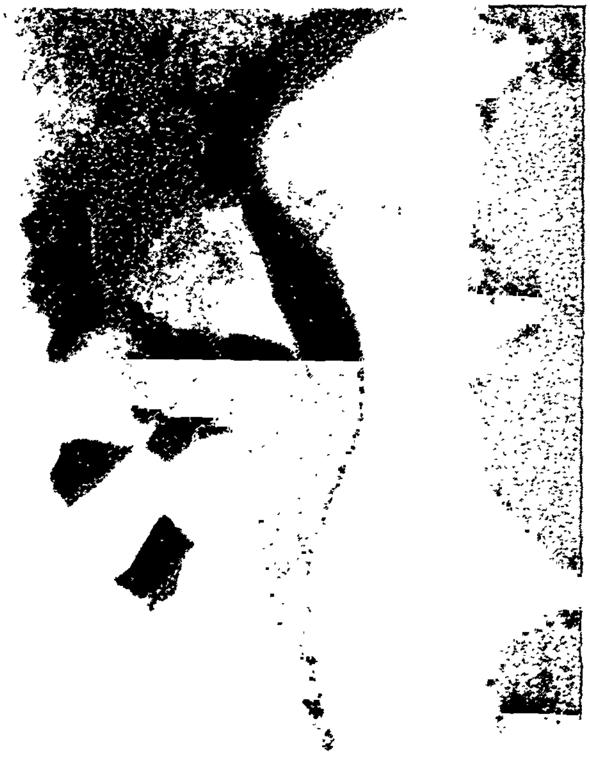

Fig. 2.—Right kidney and upper ureter on intravenous pyelogram taken in March, 1953.

SUMMARY

A patient with chronic pyelonephritis and pyeloureterocystitis cystica due to Aerobacter aerogenes was treated with intramuscularly given neomycin for two years, with complete remission of clinical symptoms, disappearance of pyuria, sterilization of the urine, and regression of the cystic lesions. Mild recurrences have been controlled with intermittent single small doses of neomycin as needed, and no significant toxic effects of the drug have been noted.

ECTODERMAL DYSPLASIA PRESENTING AS FEVER OF UNKNOWN ORIGIN

Frank C. Stiles, M.D.
and
James R. Weir, M.D., Monroe, Wis.

One cause of fever of obscure origin may be ectodermal dysplasia of the anhidrotic type. The absence of sweat glands and other characteristic features may be easily overlooked. In the case presented, as in similar cases, many months elapsed before the diagnosis became apparent.

REPORT OF A CASE

A white male infant, aged 11 months, was brought to the Monroe Clinic on Feb. 24, 1954, because of bouts of unexplained fever since birth. The history revealed that the child had been delivered by cesarean section during the eighth month of the mother's pregnancy. This delivery was performed because of the development of an obstetric complication, the exact nature of which is not known. The infant weighed approximately 6 lb. (2,721.55 gm.) at birth. Shortly after birth the child developed a skin rash and was described as being a feeding problem. It was then noticed that the child began to run unexplained bouts of fever. The parents took the boy home from the hospital after a two and one-half week period. He remained at home four days. During this time his temperature was elevated intermittently. The child was returned to the local hospital, where no obvious cause of the fever was found. The child was then referred to another hospital. Except for a one-month period at home, the child remained in this hospital for the next seven months. During this time the child ran intermittent bouts of fever and was frequently hoarse. Numerous diagnostic procedures were performed, and many antibiotics were administered. Cultures from the larynx showed various organisms on different occasions. Endamoeba coli, Micrococcus pyogenes var. aureus, and hemolytic streptococci were isolated. These were not sensitive in vitro to streptomycin, oxytetracycline (Terramycin), cloramphenicol (Chloromycetin), chlortetracycline, or penicillin. Because of the laryngeal condition, the child was referred to an ear, nose, and throat specialist who found only a mild laryngitis. Throughout one week of observation, the child's temperature was normal. Culture at this time showed the presence of Pseudomonas aeruginosa. No significant abnormality to which the fever could be attributed was found. During the next three-month period while the child remained at home, he ran frequent bouts of fever to 103 F. Various antibiotics were prescribed for these fevers.

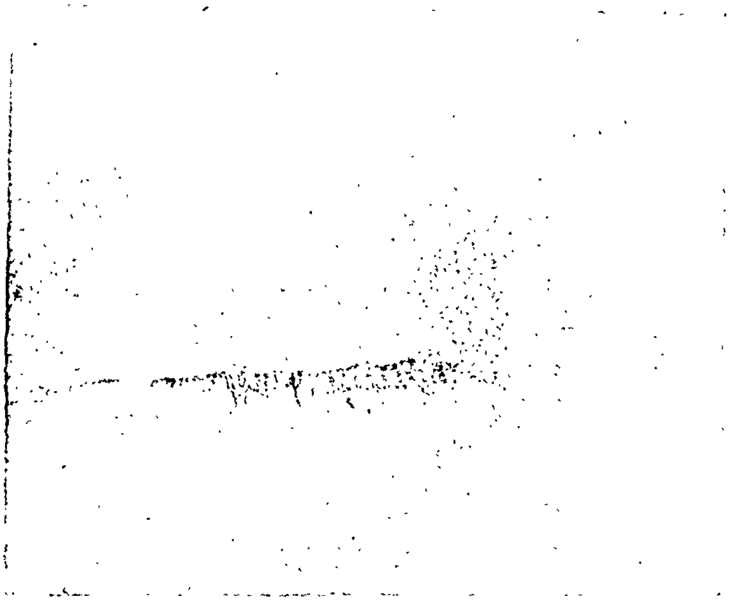

Fig. 1.—Peculiar wrinkling of skin around eyes and total absence of eyebrow hair in patient, aged 11 months, with ectodermal dysplasia.

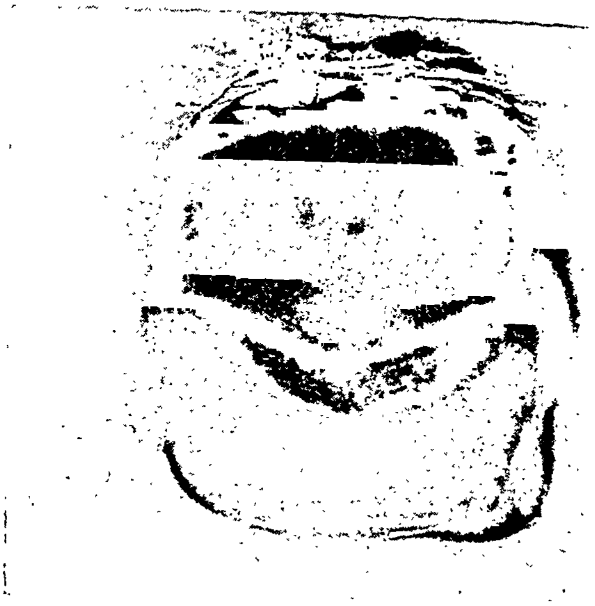

Fig. 2.—Mouth of child with ectodermal dysplasia showing hypoplasia of alveolar processes and abnormal dentition.

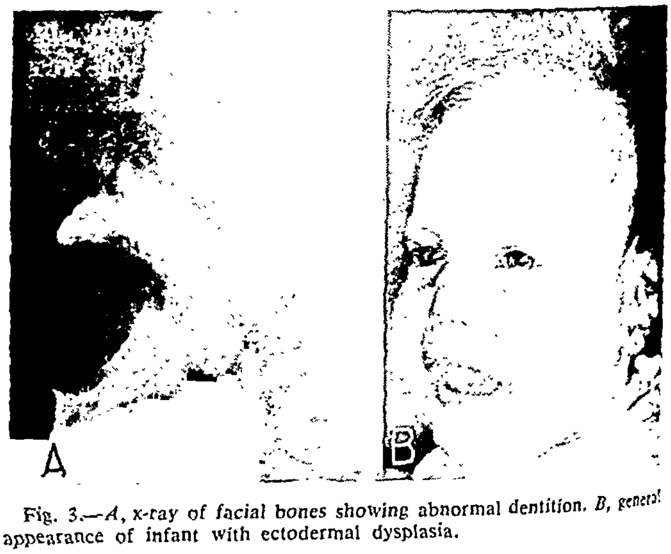

Fig. 3.—*A*, x-ray of facial bones showing abnormal dentition. *B*, general appearance of infant with ectodermal dysplasia.

Physical examination showed a well-developed, well-nourished white boy who appeared to be in surprisingly good condition, in view of his history. He seemed to have a normal mentality for an infant of 11 months. The child was of very fair complexion. A slight eczema was present on both cheeks on the initial examination, and the child's skin did not look normal. The skin was thin and translucent; it appeared somewhat dry and loose. There was an unusual and noticeable wrinkling about the eyes (fig. 1) that gave the infant the appearance of "a little old man." The hair was sparse and of fine texture. No eyebrows were present. The eyelashes of the lower lids were very sparse. A saddle deformity of the nose was present. The forehead was prominent but not abnormal for this age. One upper central incisor had erupted. This showed a brownish discoloration and was definitely peg-shaped (fig. 2). The alveolar processes were poorly developed. The child had a slightly hoarse cry. A definite concavity (so-called spoon-shaped deformity) of the fingernails on the first fingers bilaterally was noted. The remainder of the physical examination revealed no significant abnormality. The fundi were carefully checked by an ophthalmologist who found no abnormality. An otolaryngologist found no laryngeal abnormality on direct examination. Beta-hemolytic streptococci were isolated from smears from the larynx. In vitro sensitivity tests showed that these were sensitive only to aureomycin and chloramphenicol but resistant to all concentrations of other antibiotics. The x-ray films (fig. 3*A*) showed a complete absence of mandibular deciduous teeth. A generating tooth bud of the mandibular first permanent molar on the left was noted. Deciduous maxillary teeth apparently present were the right first and second molar and the left first molar; the right and left incisors were malformed. No abnormality in the blood cell count or urinalysis was noted.

On the first hospital day, before the diagnosis had been made, the child's temperature went to 103 F, rectally, but returned to normal later in the day. The child's room was kept at 68 F for the next three days and the temperature remained normal. On the fourth day, approximately one-fourth of the child's surface was painted with a 0.5% iodine solution. Starch powder was then applied to these areas. The room temperature was purposely elevated to 95 F. Within 90 minutes the child's temperature became 102.5 F rectally. There was no evidence of sweating in any area covered by the starch-iodine indicator system. The fever subsided over a two-hour period after the environmental temperature returned to normal. A final diagnosis of ectodermal dysplasia of the anhidrotic type was made (fig. 3*B*).

COMMENT

The long hospitalization of this patient afforded the opportunity to note fluctuations of the daily temperature and correlate these with the environmental temperatures during the summer months (fig. 4). It was observed that when the environmental temperature exceeded 90 F, the rectal temperature of the patient exceeded 102 F for that day. There are other factors that may have influenced the body temperatures, such as painful diagnostic procedures that caused crying and increased body activity, but, in general, the correlation with environmental temperature was very close. The temperature spikes with abrupt falls to normal seen in this patient are not characteristic of temperature increases due to a recurrent infectious process. The drops in the temperature in this case were usually attributed to the effect of an antibiotic. Some similar cases have been studied for long periods with the true diagnosis not reached until adult life.

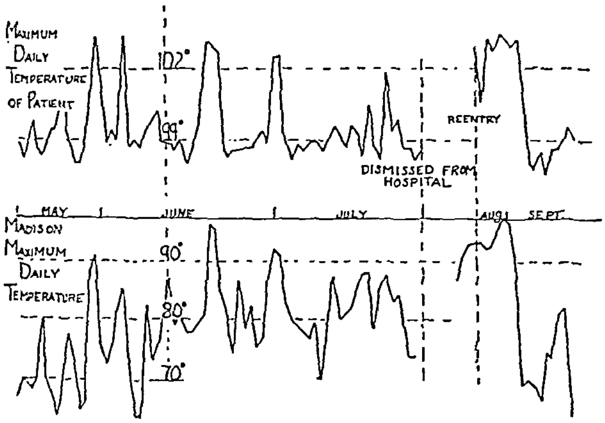

Fig. 4.—Correlation between fever and environmental temperature in case of infant with ectodermal dysplasia.

In one instance, because of a positive Mantoux test associated with an irregular temperature, a boy was advised to enter a sanatorium for the treatment of tuberculosis. The temperature irregularity of persons with ectodermal dysplasia has been studied; the rapid response to temperature of the surroundings has been noted by others and has been mentioned in most reports of this disorder. Sunderman [1] has reviewed temperature phenomena caused by the absence of sweat glands. It is difficult to prove a total absence of sweat glands. In the case reported, there was not sufficient moisture produced in a heated room to activate the starch–iodine test, which was easily exhibited by normal individuals exposed to the same temperature conditions.

This child also presented symptoms of laryngitis, which, in addition to the fever, were the only findings suggestive of an infectious process. It is, noted that symptoms of chronic rhinitis and laryngitis have been reported in other cases of ectodermal dysplasia of the anhidrotic type. In one case reported by Upshaw and Montgomery,[2] these symptoms were severe enough to necessitate a tracheotomy. The hoarseness and laryngitis may be due to a deficiency in the secretory functions of the glands of the mucous membranes of the nose and throat. However, the drying effect on the mucous membranes by the frequent high temperatures and associated rapid respirations may also aid in producing these symptoms. The peculiar wrinkling of the skin about the eyes may give the first clue to the underlying ectodermal defect in younger children. The skin is more than usually sensitive to irritants, and the mild eczema that this child had is typical of most cases.

The care of these children is directed to the control of the pyrexia by sponging or moistening the clothing in hot weather. Persons with this disease can never attempt to do heavy work during hot weather. The frequent upper respiratory infections often require professional treatment. Dental care is also necessary early, because of the absence or irregularity of the teeth, which may interfere with proper nutrition and facial growth. The development of the facial growth of one such patient, who was fitted with dentures at the age of 6, has been described by Sarnet and co-workers.[3] They have noted that the facial bones seem more fragile than normal. Abnormal dentition is one of the characteristic features of this syndrome with either total absence of teeth or the presence of peg-like structures, as noted in this child. The atrophic alveolar process associated with thickened lips and a saddle nose causes persons with this syndrome to have a striking resemblance to each other. Although this condition is known to be familial, no family history of any similar disorder was obtained in this patient.

Enzyme Treatment of Wounds.—The use of depolymerases of streptodornase in the treatment of infected wounds has produced faster healing than has occurred in similar wounds not treated with the enzymes. The digestion of desoxyribonucleoprotein and desoxyribonucleic acid has not produced substances which are toxic or detrimental to the healing of wounds. The depolymerases of streptodornase, by their enzymatic properties, effect the digestion of desoxyribonucleoprotein and desoxyribonucleic acid, when the compound can be brought into direct contact with pus for a sufficiently long period. The digestion of pus by the depolymerases of streptodornase and the removal of the pus facilitates the formation of healthy granulation tissue and the earlier healing of infected wounds.—J. M. Miller, M.D.; M. Ginsberg, M.D.; J. A. Surmonte, M.D.; F. B. Ablondi, A.B., and J. H. Mowat, Ph.D., Clinical Use of the Depolymerases of Streptodornase, *United States Armed Forces Medical Journal*, July, 1955.

POSTOPERATIVE RECURRENCE OF CANCER OF COLON DUE TO DESQUAMATED MALIGNANT CELLS

Alfred A. Pomeranz, M.D.
and
John H. Garlock, M.D., New York

The dissemination of cancer during operative resection is a problem of fundamental importance and one that has occupied the attention of surgeons for generations. The principles of meticulous handling of tissues and en bloc resection were established early in the modern surgical era and rapidly applied to the resection of all somatic neoplasms. Such techniques, however, are not readily applicable to visceral neoplasms, particularly those of the gastrointestinal tract, where greater attention has been paid to permeation along lymphatic channels than to the possible local implantation of viable cancer cells. In a recent review of suture line recurrences after anterior resection of the rectum, Goligher and associates[1] analyzed 23 cases, 16 from a series of 162, or 10%, and 7 additional cases from other sources. They concluded that in at least half of these 23 cases the recurrence was not due to incomplete resection of intramurally spread tumor but rather to the implantation of viable cancer cells lying free in the lumen of the distal rectal stump upon the raw surfaces of colon presenting at the anastomosis. That this phenomenon is not peculiar to the operation of anterior resection but occurs in resections elsewhere in the colon was demonstrated in two additional patients, in one of whom a resection of the splenic flexure was done and in the other a colectomy and ileosigmoidostomy.

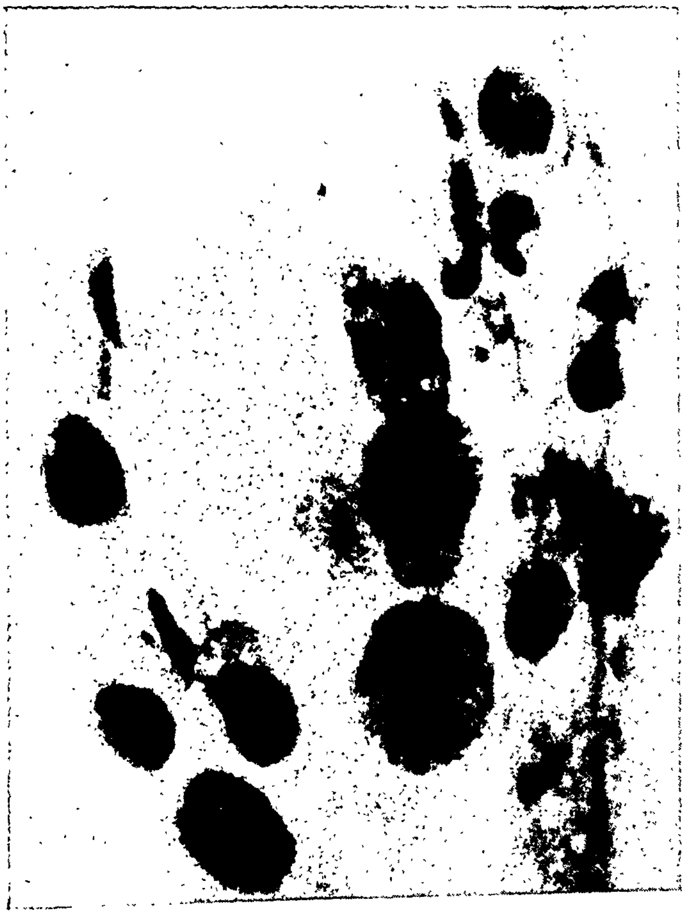

Fig. 1.—High-power photomicrograph of malignant cells obtained by use of simple smear technique. Large hyperchromatic nuclei with multiple large nucleoli and poorly defined cytoplasm are seen in center and normal serosal cells at top and below.

The recent work of McGrew and associates[2] establishes the probable way this process works. By the use of cytological techniques it was demonstrated that well-preserved and apparently viable malignant cells were present in smears of 42% of the proximal ends and 65% of the distal ends of the resected colons at average distances from the tumors of 21 cm. and 10 cm., respectively, and at 35 cm. from the tumor in one instance. The evidence further indicated that dissemination of the malignant cells occurred as a result of operative manipulation and not by peristalsis or preoperative enemas. McGrew and associates therefore advocated the use of occlusive ligatures around the colon, proximal and distal to the tumor, before any manipulation and resection of the tumor-bearing segment of the colon was begun. The conclusive results of this study leave little doubt as to the mechanism of suture line recurrence.

In recent years we have encountered several cases of recurrent tumor nodules that appeared in the abdominal wounds of patients who had undergone colon resection for carcinoma. A similar occurrence was noted in one of the cases reported by Goligher. The nodules appear at varying intervals after surgery. The most recent recurrence we have observed appeared 11 months after ileocolic resection for a tumor of the hepatic flexure. The nodules may reach a size of several centimeters in diameter, are entirely confined to the abdominal wall, and are in no way continuous with the viscera or with other intraperitoneal recurrences that may have appeared. That these recurrent nodules are the result of lymphatic permeation seems unlikely, since they do not lie in the course of any of the established lymph channels of the colon. On this service great care is exerted to isolate and pack off the segment of colon to be resected from the time of transection of the colon to completion of the anastomosis so that implantation of cells from the lumen of the colon seems unlikely.

Direct invasion through the full thickness of the antimesenteric walls of the colon and involvement of the subserosal lymphatics is a common occurrence in carcinoma of this organ. These nests of malignant cells are in turn covered by no more than a solitary layer of serosal cells. It has been the belief of one of us (J. H. G.) for some time that viable malignant cells can be rubbed off the serosal aspect of colonic neoplasms during operative manipulation, not only by relatively rough gauze pads and sponges but also by the surgeon's gloves. That it is relatively simple to dislodge the serosal cell barrier and also malignant cells is demonstrated in the results described below. If this is accepted, then it is not difficult to visualize the implantation of these malignant cells into the relatively unprotected abdominal wall, a tissue-culture medium equally as fine as the raw edges of the transected colon of an anastomosis.

From the Surgical Service of the Mount Sinai Hospital.
Dr. Louis Lapid and Miss Rita Chergoff assisted in this study.

TECHNIQUES

An effort was made to recover desquamated cells in much the same manner that they might be mechanically dislodged during surgery. Smears were taken from the serosal aspect of the colonic tumor as soon as the peritoneal cavity was entered and before any manipulation of the tumor was carried out. Smears were taken by two methods: 1. One end of a glass slide was pressed to the surface of the tumor and gently pulled across its surface to the full extent of the slide. 2. Sterile, cotton-tipped applicators were rubbed across the tumor in a fashion simulating a gauze sponge. In this latter technique the cotton tips were gently rolled across glass slides in an effort to minimize further trauma to the cells. Two of each type of smear, four in all, were taken for each tumor. The slides were immediately prepared by the use of the Papanicolaou technique [3] and carefully studied for malignant cells.

Fig. 2.—Malignant cells from same tumor as figure 1, recovered by cotton-tipped applicator and transferred to a glass slide.

RESULTS

In the past two years smears were taken from 20 unselected cases of carcinoma of the colon coming to surgery. The tumors studied were located in all sections of the colon and invariably had invaded the full thickness of wall, producing the characteristic puckered serosal surface. Unmistakable carcinoma cells were recovered from two tumors (10%), both of the sigmoid colon. In one, a positive smear was obtained only by use of the slide-smear technique, while in the second a positive slide was obtained by use of both the smear and the cotton-tipped applicator techniques. In general the cotton applicator method gave poorer slides where considerable cell destruction was encountered. It was surprising, indeed, to note the large plaques of well-preserved serosal cells so readily removed by simply running a clean, dry slide across the tumor.

As in the experience of McGrew and associates the cytoplasm of the malignant cells we recovered was poorly outlined or absent. The nuclei, however, were well preserved and conformed well to the criteria for malignancy outlined by Papanicolaou, viz., disproportionate nuclear enlargement, hyperchromasia and chromatin abnormalities, giant nucleoli, and multinucleation. No abnormal mitoses were encountered. Although malignant cells were infrequent on any one slide, they were found in small clusters (fig. 1 and 2) and compared closely with published examples from similar tumors.[4]

COMMENT

It is apparent from this study that malignant cells rubbed free from the serosal aspect of tumors may not only cause abdominal wall recurrences but also represent a grave danger to dissemination and implantation within the peritoneal cavity. In an effort to obviate this hazard, a colon cover was designed, which not only protects the serosal aspect of the tumor from manipulative trauma but also combines the occlusive ligatures at a distance from the tumor, as recommended by McGrew and associates. The covers in present use are modified from ordinary gauze abdominal pads. They are 11 in. long, wider in the center than at the ends, and of sufficient capacity to surround the tumor-bearing portion of colon at the center and the uninvolved part at each end. The center and each end are furnished with a long, heavy silk ligature that is passed through the mesentery immediately adjacent to the colon and then tied snugly around it. Figure 3 illustrates the use of such a cover. Except in very large, bulky tumors it is usually possible to tie the ends around uninvolved colon approximately 4 in. (10 cm.) from the tumor. In freely dependent colon as the sigmoid, the cover is applied as soon as the peritoneal cavity is entered. In other segments it is applied as soon as the lateral peritoneal attachments are severed.

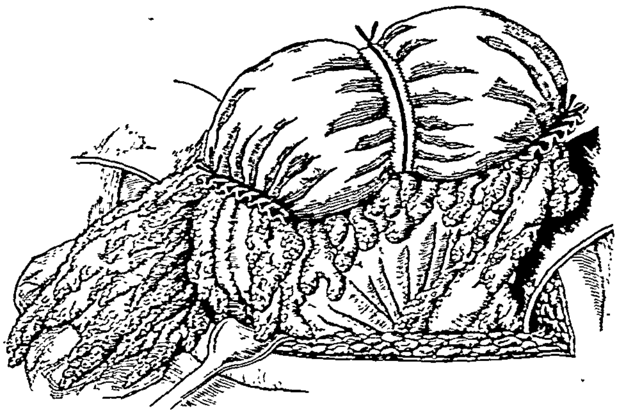

Fig. 3.—Colon cover applied to a tumor of the right transverse colon after incising the gastrocolic ligament.

CHEMOTHERAPY AND "VANISHING LUNGS"

Israel Rappaport, M.D., New York

An unsuspected relationship between chemotherapy and "vanishing lungs" is now attracting much attention in centers devoted to treatment of pulmonary diseases. Perhaps the simplest way of describing this phenomenon is to say that pulmonary processes resolving under the effect of chemotherapy leave in their wake thin-walled abnormal air spaces now commonly designated as "cyst-like cavities." These have also been described as "vanishing lungs," a truly descriptive name. This remarkable phenomenon has been reported from many places and described uniformly as a new development in pulmonary pathology, raising questions of practical as well as theoretical nature. Practically, are we dealing with a new development? I definitely believe not. Even before chemotherapy was practiced, numerous observations were reported of vanishing lung areas affected by a variety of pulmonary processes; however, there is no doubt but that the incidence has greatly increased in recent years. It has also become apparent that more complete resolution of pathological products in the lungs, with chemotherapy, is in some manner connected with this phenomenon. In a recent review of this subject, Mayer and myself [1] pointed to the rising incidence of air space abnormalities with the advent of chemotherapy.

In abscesses as well as in tuberculosis, confluent extensive processes as a rule result either in thick-walled cavities or in dense fibrosis. Now, chemotherapy often

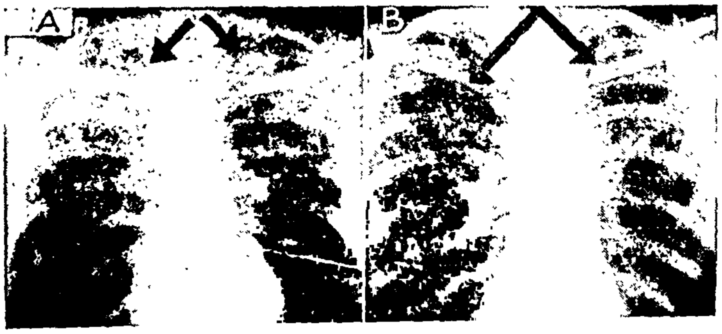

Fig. 1.—Roentgenograms of tuberculous patient, a man in his late 20's. arch, 1950, extensive lesions in both upper lobes are shown. *B*, in 1954, tuberculous lesions resolved in both lungs are replaced anished lung.

resolution before any of these
articularly true for the effect
processes in the predominantly exudative phase. Cyst-like cavities have been observed to develop particularly in patients with such processes.

CLINICAL AND MORPHOLOGICAL FINDINGS

In pulmonary tuberculosis, the cavity has always been a practical clinical problem of great concern; it is therefore only natural that cyst-like cavities, appearing upon

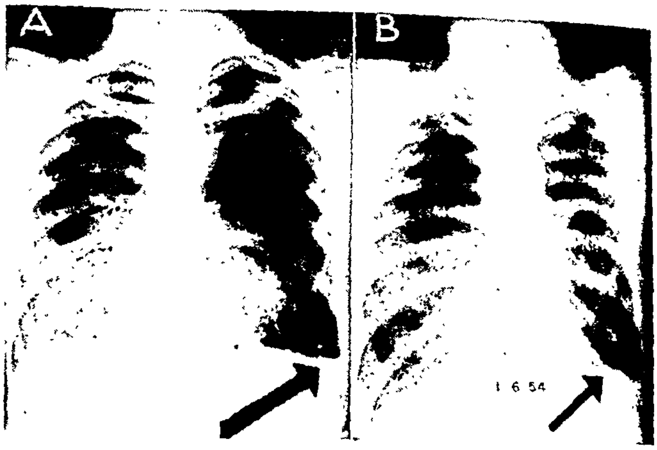

Fig. 2.—Roentgenograms of man in late 30's with marked features of vanishing lungs. *A*, in June, 1953, a large pneumatocele in base of left lung with fluid level shown. *B*, in January, 1954, reversibility of condition with reexpansion of compressed lung areas is shown.

resolution of tuberculous processes, are now causing much concern. The immediate question is that of their clinical significance. Are the bearers of such residual cyst-like cavities cured or not cured of their disease? Answers to these questions are now sought from clinical follow-up of patients and from morphological studies of surgical specimens. Clinical observations indicate that in a large proportion of cases these abnormal air spaces show marked reversibility. They may even become completely deflated after a long state of hyperinflation or revert to the status of typical tuberculous cavities. In many cases the status of vanishing lung develops and persists. Morphological findings include evidence for so-called open healing of tuberculous cavities as well as evidence of truly emphysematous air spaces. The former are more or less characterized by reepithelialization from the broncho-cavity junction; the latter show continuous fibrosis tissue lining without epithelialized or necrotic parts. Both types of airspaces may be found next to one another in the same specimen. Morphological evidence for bronchial obstruction is conspicuously absent in these specimens.

From these observations it is apparent that in tuberculous processes healing under chemotherapy, two distinct types of abnormal air spaces develop. Presumably, in an already caseated lesion, open healing of more or less completely sterilized cavities occurs. Emphysematous changes resulting in vanishing lungs seem to occur particularly in healing of lesions not yet caseated. Reversible hyperinflation is undoubtedly best accounted for by bronchial obstruction. This has led to the assumption that bronchial obstruction accounts for all the air space abnormalities observed in the healing of tuberculous processes under the effect of chemotherapy. Air space abnormalities that develop under clinical observations are practically always looked upon as forms of obstructive emphysema, despite the fact that there is no evidence for the presence of bronchial obstruction at the

---

ws, J.
ce of
ations and Interpre-
pt of Their Origin,

beginning of the emphysematous process and that there is ample evidence against it as playing the main role even in the subsequent evolution of emphysematous changes.[1] It will bear repetition at this point to say that, in recent large-scale observations, the morphological findings have also failed to produce evidence for bronchial obstruction. Although reversible hyperinflation of abnormal air spaces indicates that bronchial obstruction plays a role in the changing state of inflation, it affords no proof of its being the primary event and sole cause of the phenomena of vanishing lungs. As the sequence of events in reversible hyperinflation is now observed in a great number of cases, the conclusion seems inescapable that inflammatory processes, even when not necrotizing in their effects, may yet damage the ultimate structures in the affected lung areas so as to cause their apparent disintegration and subsequent absorption together with the pathological products. Chemotherapy, by preventing development of dense fibrotic residues and by favoring more complete self-cleansing of the affected area, has made this phenomenon conspicuous now.

NATURE AND ORIGIN OF AIR SPACE ABNORMALITIES

The fundamental problem is obviously that of the nature of the primary phenomenon in vanishing lungs, which is now submerged in the broad problem complex of the nature and origin of pulmonary emphysema, in general. As I have pointed out in recent publications,[1a] it is now widely realized that prevailing concepts about obstructive emphysema do not afford an adequate solution for the problem of emphysema. The problem of the vanishing lung under the effect of chemotherapy in tuberculosis remains to be solved. On the basis of a new concept of lung function proposed by me [2] nearly two decades ago, I offered reasonable explanations of the nature and origin of air space abnormalities, as they are now observed under a variety of clinical conditions. Referring to recent publications [3] for the detailed discussion of the nature and origin of these abnormalities, I would like to comment on the following points. The phenomenon of vanishing of affected lung areas has been predicted as implicit in the concept of visceral lung function, which assumes that breathing surface creation, by partitioning of the air spaces, and their constant self-cleansing constitute the activities of the ultimate lung structures. These twin functions are so correlated that, where partitioning ceases, the structures disappear in the continuous self-cleansing process that maintains the breathing surface intact. In any lung area, visceral function may be inadequate because of defective postnatal development, or it may become defective due to subsequent changes, pathological or involutional. Normal thoracic traction acting upon such defective air spaces, lacking adequate partitioning function by the parenchyma, will overdistend these to the point of failing elastic recoil. Air spaces so overdistended constitute what we recognize as emphysema, in the origin of which the primary factor is the "lung defect." The nature of this varies according to the three phases of life. In early life the lung defect is mostly "developmental" in origin.[3a] During adult life lung defects are "acquired" by a great variety of pathological processes.[1] In old age emphysema develops on the basis of the "involutional" lung defect.[3b] Combinations of these lung defects frequently play a role in the pathogenesis of vanishing lungs. After childhood, in many cases, development of the acquired defect is favored and exaggerated because the pathological process, such as tuberculosis or abscess, has involved lung area already previously affected by latent developmental defect. Senile emphysema often develops because the involutional defect is exaggerated by preexisting acquired lung defects.[3b]

The manner in which air space disorder and the picture of vanishing lungs develop on the basis of emphysema complicated by air passage obstruction becomes quite obvious from the foregoing. The very nature of the process by which emphysema is produced leads secondarily to bronchial obstruction, with check valve mechanism and reversible hyperinflation of already abnormal air spaces. It should also be quite obvious that lungs harboring abnormal air spaces will naturally predispose to complicating infections, which may also often lead to secondary bronchial obstruction and its sequelae. Incomplete bronchial obstruction will exaggerate the air space abnormality and result in large bullae or air cysts. Complete obstruction accounts for reversal or occasional complete disappearance of abnormal air spaces. The literature is replete with reports on observations of both sequences of events. While vanishing of lung areas upon resolution of tuberculous processes is now a common observation, less common is the observation of tuberculous processes appearing in previously vanished lung areas, leading to reversal of the sequence of events. Recently, observation of the occurrence of the latter also has been reported. As an example of the first sequence of events, figure 1 shows the resolution of tuberculous lesions resulting in vanishing lungs; figure 2 illustrates the second sequence of events, showing disappearance of a large hyperinflated air space, upon resolution of a complicating infection, as indicated by fluid level. My observations lead me to believe that the infectious process that was originally responsible for the development of vanishing lungs may persist and relapse in the bronchi even after long intervals. This is probably true particularly for tuberculous processes.

Regarding the treatment of cyst-like cavities, practical conclusions to be drawn from the foregoing should be obvious. Radical surgical resection is indicated whenever feasible, as cyst-like cavities of known tuberculous origin are potential sources of flare-up in a large proportion of cases. Vanishing lung areas are potential sites for progressive air space disorders, with all the dangerous complications of progressive pulmonary failure, as recently described in my discussion of that subject.[4] It seems a measure of sound prevention to deal with such air space abnormalities before they progress very far.

SUMMARY

The phenomenon of "vanishing lung" is now commonly observed upon resolution of disease processes in the lungs under the effect of chemotherapy. Most of these observations are now made in cases of pulmonary tuberculosis in predominantly exudative processes, when streptomycin and particularly isoniazid prevent caseation as well as dense fibrosis and promote more complete resolution of pathological products.✓ The current trend is to explain this as a phenomenon of obstructive emphysema, in spite of the fact that there is neither clinical evidence of bronchial obstruction before its development nor evidence for such obstruction in the subsequent morphological findings. The point is made here that this puzzling phenomenon must be explained on the basis of a solution of the broad problem complex of pulmonary emphysema. It is now widely realized that the concept of obstructive emphysema does not afford an adequate solution for the phenomena of pulmonary emphysema in general. The vanishing lung phenomenon is implicit in a new concept of lung function. It seems to offer a reasonable explanation of the nature and origin of pulmonary emphysema.

ROLE OF SURGERY IN THERAPY OF ADRENOCORTICAL HYPERSECRETION

Harry H. LeVeen, M.D.
and
Alton R. Pruit, M.D., Roswell, N. Mex.

In the female, hirsutism is common to both adrenocortical hyperfunction (Cushing's syndrome) and the adrenogenital syndrome. In the latter, virilism, slight obesity, and nitrogen retention are additional outstanding features. The virilism is manifest by voice changes, darkening of the skin, increased muscularity, hypertrophy of the clitoris, growth of a beard, occasionally male type of baldness, atrophy of the breasts, amenorrhea, and uterine and ovarian atrophy. Patients with adrenogenital syndrome usually do not exhibit those changes that occur with adrenocortical hyperfunction. These are hypertension, truncal and facial obesity, carbohydrate intolerance, osteoporosis, purplish striae, alterations in sodium-potassium ratio in the serum, and alterations in endogenous protein metabolism as evidenced by changes in uric acid and creatinine excretion. In both of these conditions, the physiological changes may be secondary to benign or malignant cortical tumors that maintain the capacity to secrete hormones. In adrenocortical hyperfunction it is impossible to differentiate between neoplasia and hyperplasia except by some method of anatomic demonstration of the tumor mass. Positive anatomic evidence is valuable in the diagnosis of tumor, but negative evidence does not exclude it. In adrenogenital syndrome, a functional test to be described can be used to distinguish tumor from hyperplasia. In other cases, neoplasm is not present and the anatomic physiological abnormalities are produced by cortical hyperplasia and hypersecretion. Most often the hyperplasia and hypersecretion are intrinsic disturbances of the adrenal gland itself, but in some cases they are secondary to a high output of corticotropin from a basophil adenoma of the pituitary.

In adrenocortical hyperfunction of primary origin, the overproduction of cortical hormones inhibits the pituitary gland, and hyalinization of the basophil cells results. This change was first described by Crooke.[1] Similar changes in the pituitary can be produced by injection of large doses of cortisone or corticotropin in experimental animals.[2] They have also been found in humans who have died in the course of therapy with corticotropin or cortisone.[3] One must conclude that adrenal steroid hormones in the circulating blood inhibit the basophil cells of the pituitary. This is true whether the steroid hormone is injected or endogenously produced as is the case when the adrenal cortex is stimulated by corticotropin. The excessive production of cortisone-like hormones by the hyperplastic gland causes an increase in the primary excretion of 11-oxycorticosteroid-like substances.[4] The urinary output of corticoids as measured by the formaldehydogenic method is usually increased.[5] Rarely is the urinary 17-ketosteroid output elevated.[6] Masculinization, which is a physiological effect of 17-ketosteroid action, is not prominent in the usual case of adrenocortical hyperfunction.

In adrenocortical hyperfunction of primary adrenal origin, the hyperplasia and hypersecretion of the adrenal gland are unexplainable; but the hyperplasia occurring with adrenogenital syndrome is understandable. Cortical cells may synthesize hydroxycortisone via many pathways, of which at least two may account for a good proportion of the biosynthesis. It may be formed directly from the ketosteroid (dehydroepiandrosterone), which is a masculinizing hormone,[6A] or it may be formed from 17-hydroxyprogesterone, which is rapidly converted to ketosteroid in the body and is therefore masculinizing. In other words, hydroxycortisone may be formed from a ketosteroid or a precursor in common.[6B] It is believed that in adrenogenital syndrome the necessary enzyme for this conversion is absent.[7] A deficiency in circulating hydroxycortisone occurs with a consequence that the normal inhibitory action of this hormone on the pituitary is lost. The pituitary responds by producing excessive quantities of corticotropin.[8] The adrenal is capable of responding to this corticotropin only

---

Dr. LeVeen is now at the Department of Surgery, Chicago Medical School, Chicago.

by the production of 17-ketosteroids, since the conversion to hydroxycortisone cannot be completed without the missing enzyme. Large quantities of 17-ketosteroid hormones now circulate in the blood and appear in the urine, but the excretion of 11-hydroxysteroids is reduced. The androgenic activity of the 17-ketosteroids causes masculinization. The sugar intolerance and other stigmas of adrenocortical hyperfunction do not appear because of the deficiency in hydroxycortisone. In these cases of adrenogenital syndrome, cortisone administration causes the 17-ketosteroid output to drop precipitously and the masculinization to disappear.[9] This result occurs by supplying the missing hormone.

Occasionally a small basophil adenoma of the pituitary produces corticotropin in excess and secondarily induces adrenocortical hyperfunction. Since these tumors are small, they usually do not produce neurological, visual, or other objective changes. The absence of objective findings makes it impossible to distinguish primary from secondary hyperplasia without a clinical test for circulating corticotropin. Unfortunately, a simple clinical test does not exist. Since one cannot distinguish between primary and secondary types of adrenal hyperplasia, many feel uncertain of the role of adrenal resection in the treatment of adrenocortical hyperfunction and prefer radiation of the pituitary. Even so, the literature does contain favorable reports on adrenal resection in this disease.[10]

Those cases of pure adrenogenital syndrome that respond fairly well to cortisone should be so treated, but what about those that do not respond favorably? More recently, Jailer has demonstrated that the normal secretion of neoplasms (both benign and malignant) is autonomous and is unaffected by corticotropin.[10a] The inhibition of endogenous corticotropin production (which is brought about by the injection of cortisone) does not bring about any reduction in the production of hormones by the tumor. In neoplasms, the urinary 17-ketosteroid output fails to drop after the administration of cortisone. This forms the basis for a test to distinguish between tumor and hyperplasia. Surgical therapy is naturally indicated only in cases of tumor.

The adrenogenital syndrome and adrenocortical hyperfunction have been discussed as if they were two separate entities, but occasionally the features are so intermingled that one is hard put to classify the disturbance. Is such a classification useful? One naturally suspects that the admixture of the two syndromes would make for confusion and preclude a satisfactory explanation for the pathogenesis in either condition. What role does the laboratory play in the diagnosis and differentiation of these symptoms? What role does surgery play in the therapy of these conditions? A case is reported that to outward appearances was one of adrenogenital syndrome. This unusual crossover case has contributed greatly to the understanding and management of these two syndromes and has provided solutions to the questions that have just been raised.

REPORT OF A CASE

This patient was a 27-year-old married woman who had originally consulted physicians with a complaint of amenorrhea. Since 1945, she had had scanty menses and finally, in 1952, amenorrhea. On several occasions, vaginal bleeding had been produced with cyclic therapy. In October, 1952, an endometrial biopsy revealed focal cystic hyperplasia, but no secretory activity. Her basal metabolic rate in October, 1953, was +8% and her blood cell count normal. She was first seen by us in April, 1953. She had no vaginal discharge, no abdominal pain, and no dyspareunia but did complain of a loss of libido. There were no voice changes. She had been gaining weight during the past year. A systemic review was normal. Her mother died of carcinoma of the uterus in her late 30's. There were no other children.

Physical Examination.—The patient was a 5 ft. 4 in. (162.56 cm.) white female, weighing 129.5 lb. (58.7 kg.) but not appearing acutely or chronically ill. The facies were slightly moon-shaped, and there was an increase in lanugo-like facial hair. The skin was not florid. There were coarse hairs in the region of the chin and on the upper lip. The voice was not deepened. The pupils were equal and reacted to light. The fundi were normal. The pharynx was pink, and the teeth were in good repair. There were few palpable cervical lymph nodes; the thyroid was not palpable. The breasts were normal, with no apparent striae. Lungs were clear to percussion and auscultation. The blood pressure was 160/110 mm. Hg. A regular sinus rhythm was heard, and the point of maximal impulse was at the fifth intercostal space at the midclavicular line. There were no thrills or murmurs, and the sounds were of good quality; the aortic second sound was greater than the pulmonic second sound. There were no abdominal striae. The liver, spleen, and kidney were not palpable, and there were no masses. The external genitalia were normal; there was no hypertrophy of the clitoris. The pelvic examination showed a very small anterior uterus with normal adnexae and cervix. The extremities were normal and showed no edema. Rectal examination was also negative. The hemoglobin was 15.5 gm. Sweat sodium concentration was 77 mEq. per liter (normal for our method in winter, 90 to 110 mEq. per liter).

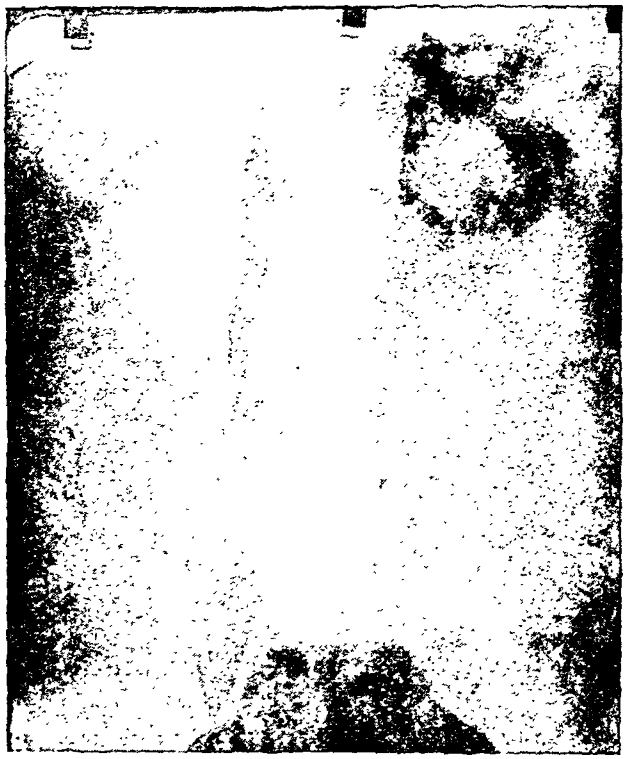

Fig. 1.—Simultaneous intravenous pyelogram and retroperitoneal air insufflation showing questionably enlarged left adrenal but no tumor masses.

[10a] Jailer, J. W.; Gold, J. J., and Wallace, E. Z.: Evaluation of the "Cortisone Test" as a Diagnostic Aid in Differentiating Adrenal Hyperplasia from Adrenal Neoplasia, Am. J. Med. 16:340, 1954.

The urine was normal. A glucose tolerance test showed, at the start, 78 mg.; in 30 minutes, 146 mg.; in 60 minutes, 94 mg.; in 90 minutes, 88 mg.; and in 120 minutes, 81 mg. An insulin tolerance test (0.1 mg. per kilogram of body weight) showed at the start, 94 mg.; at 30 minutes, 59; at one hour, 42; and one and a half hours, 75; and at two hours, 94. The 17-ketosteroid determination showed 31.5 mg. for 24 hours (normal, 6 to 15 mg.). An x-ray of the skull and bones was negative. There was no osteoporosis. The visual fields were normal.

Course.—The patient's blood pressure over a period of four months remained elevated, reaching as high as 200/110 mm. Hg. The hirsutism and truncal and facial obesity became more marked. The patient was given cortisone therapy with the tentative diagnosis of adrenogenital syndrome. She was given 12.5 mg. of cortisone four times a day. The 17-ketosteroid level with this therapy stayed at 39 mg. per 24 hours. The fact that the 17-ketosteroid level was not influenced by this therapy suggested that an adrenal tumor might exist. Another test for 17-ketosteroid excretion showed 40.3 mg. The patient was then placed on a high dosage of cortisone intramuscularly for one week, 100 mg. per day. Before discontinuance of cortisone therapy, the 17-ketosteroid excretion was again tested and was found to be 30.6 mg. Although this was a slight drop, it was thought that the patient had an adrenogenital syndrome secondary to an adrenal tumor. A retroperitoneal air insufflation was done but did not confirm the presence of any sizable tumor (fig. 1).

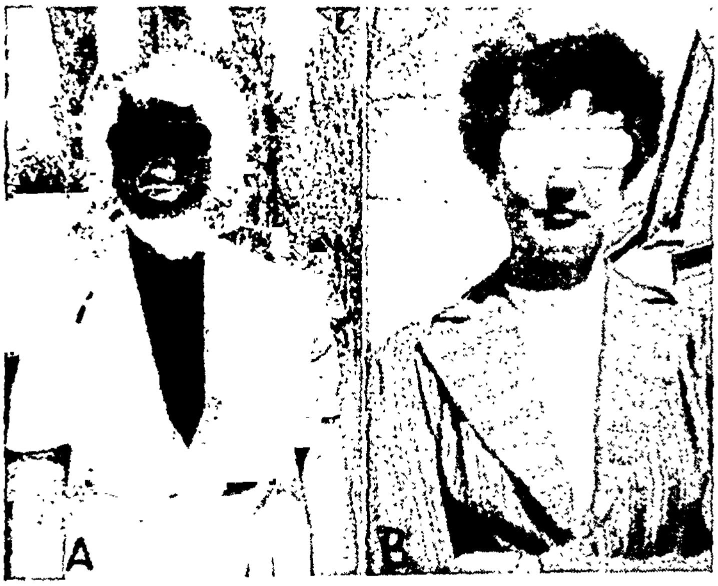

Fig. 2.—*A*, Preoperative photograph of patient in case reported showing moon-shaped facies and hirsutism. *B*, three and a half months after operation, showing loss of facial adiposity and hair.

The patient was prepared for two days preoperatively with cortisone according to the method used by Bergenstal and Dao.[11] On Nov. 9, 1953, both adrenal glands were explored and no tumor was disclosed. Both glands appeared slightly larger than normal, the left being much larger than the right. The abdominal cavity was likewise explored. The uterus and ovaries were found to be extremely atrophic. In addition, a few small omental cysts were found that proved on pathological examination to be dilated lymphatics. The adrenals were subtotally resected on both sides, leaving approximately a 1 cc. portion on each of the sides. The weight of the resected adrenal was 17.9 gm. on the left and 8.5 gm. on the right (combined weight of over 15 gm. is considered hyperplasia). The pathological diagnosis was hyperplasia of the left adrenal.

Postoperative Course.—The patient made an uneventful recovery, and except for a severe episode of influenza her convalescence was good. The postoperative sweat test showed 98 mEq. per liter, which is considered normal. A Kepler water tolerance test, done postoperatively to make sure that the patient had no adrenal insufficiency, was negative. The postoperativ blood sugar level was 98 mg. per 100 cc. The patient's bloo pressure dropped from levels ranging from 200/110 mm. H preoperatively to 124/84. Her weight dropped from 130 to 11 lb. (59 to 54 kg.) in five months. The hirsutism disappeared Three postoperative 17-ketosteroid determinations were done an were 7.6, 8.7, 6.3 mg. These determinations were done at weekl intervals and showed that there was no evidence of regeneratio and that a satisfactorily functioning residue was left. The trunca and facial obesity disappeared, as shown in the photograph (fig. 2). Patient had spontaneous onset of menses, which starte as spotting on the fifth postoperative day. Since that time sh has had regular menstrual periods, with a normal flow. Her headaches, which were probably secondary to hypertension, di appeared. Her only complaint remained stiffness in her joint which was relieved by salicylates. The sedimentation rate remain normal. The patient has shown no evidence of recurrence on year postoperatively. She became pregnant four months aft surgery but had an early spontaneous abortion.

COMMENT

In this case, the only early manifestation of disorde was mild virilism, amenorrhea, and sterility extendin over a period of several years. There were no early stigmas of adrenocortical hyperfunction, although some appeared later in the progression of her disease. Superficially, the clinical appearance suggested the diagnos of adrenogenital syndrome. This was partially confirme by a high 17-ketosteroid excretion. The fact that th 17-ketosteroid output did not drop after the administr tion of cortisone in adequate dosage suggested the po sibility of a cortical tumor and illustrates an appare shortcoming in the use of this test. In spite of the ou ward appearances, we believe that the patient should b considered as having had adrenocortical hyperfunctio even though she had almost none of the changes that a usually found. The only late stigmas of adrenocortic hyperfunction were hypertension and moon-shape facies.

The formation of hydroxycortisone may be repr sented by the following simple equation.

$$\begin{tikzcd}
 & \textit{17-ketosteroids} \\
\textit{Steroid precursor} \arrow[ur, "k_1"] \arrow[dr, "k_2"'] & \\
 & \text{hydroxycortisone}
\end{tikzcd}$$

The rate of production of 17-ketosteroids will depen upon the rate at which cells transform the precurso (k_1) in the equation. The rate of formation of hydrox cortisone will depend upon the rate of conversion (k_2 in the equation. The production of more precursors tha could be rapidly converted to hydroxycortisone woul cause an excess conversion to ketosteroid. In othe words, the amount of masculinizing ketosteroid that i formed would depend upon the ratio k_1/k_2. With a hig ratio, masculinization would be expected; when the rati is low, minimal virilism, if any, would occur. If hydro cortisone is synthesized directly from ketosteroid (deh droepiandrosterone), the rate of conversion of thi masculinizing hormone would determine whether viri ism would occur. In the male, the same should apply but the tendency may be toward feminization, since th overproduction of adrenal hormones inhibits the pituitary sufficiently to depress the pituitary output of gonadotrophin. This results in reduced output of mal sex hormone by the testes.[12]

[12] Wilkins, L., and others: Further Studies on Treatment of Congenital Adrenal Hyperplasia with Cortisone: Effects of Cortisone on Sexual and Somatic Development, with Hypothesis Concerning Mechanism of Feminization, J. Clin. Endocrinol. 12: 277, 1952.

A distinction may be made between the two conditions. A female patient even with virilism should be considered to have adrenocortical hyperfunction if she partakes of any of the clinical features of this disease. The converse is also true. A patient with pure adrenogenital syndrome cannot exhibit any of the clinical features of adrenocortical hyperfunction. It is evident that a patient with adrenocortical hyperfunction might have mixed findings, but an adrenogenital syndrome must be a pure syndrome. Adrenocortical hyperfunction should be treated by adrenal resection along with those cases of adrenogenital syndrome that do not respond to cortisone.

The present status of adrenal gland resection should no longer be a point of disagreement. Adrenocortical hyperfunction is a rapidly fatal disease with an ultimate average prognosis of five years from the onset of symptoms.[13] On the other hand, adrenocortical hypofunction (Addison's disease) induced by the relatively simple and nonlethal surgical extirpation of the adrenal glands is proving to be a mild and easily manageable disease even in elderly debilitated patients. Therapy in adrenocortical hyperfunction may be likened to surgical therapy in hyperthyroidism. Some cases of hyperthyroidism are of pituitary origin. These cases can be distinguished by the type of exophthalmos.[14] Other cases of hyperthyroidism are due to primary thyroid hyperplasia and hypersecretion.[15] The hyperthyroidism in both types of case responds well to subtotal thyroidectomy, providing sufficient tissue is removed. Similarly, those cases of adrenocortical hyperfunction that are secondary to basophil adenoma of the pituitary would also be relieved. Since these basophil adenomas so rarely produce symptoms because of their small size, the analogy to hyperthyroidism of pituitary origin is not far-fetched. Adrenocortical hyperfunction secondary to primary glandular hyperplasia is analagous to hyperthyroidism of primary thyroid origin. Past failures with adrenal resection must be attributed to insufficient removal of the adrenal glands, a situation that occurred in the early trials with thyroidectomy for hyperthyroidism.

What role does the laboratory play in diagnosis and treatment? The response of the 17-ketosteroid output to the injection of cortisone may aid in distinguishing between tumor and hyperplasia in the adrenogenital syndrome. It is also useful in the regulation of the dosage of cortisone in the adrenogenital syndrome. Further than that, the laboratory is not of fundamental importance. The decision as to the method of treatment must be decided on the basis of the clinical findings.[16]

SUMMARY AND CONCLUSIONS

A case of adrenal hirsutism that partakes of any of the features of adrenocortical hyperfunction (Cushing's disease) must be treated as such even if the virilism is prominent enough to suggest the diagnosis of adrenogenital syndrome. The adrenogenital syndrome will not have any of the features of adrenocortical hyperfunction. Subtotal adrenalectomy is the therapy of choice for adrenocortical hyperfunction and for those cases of adrenogenital syndrome that do not respond to cortisone.

ADDENDUM

Since the submission of this article, the patient has delivered a premature but otherwise normal infant. The antepartum course and parturition were uncomplicated. The patient was given 50 mg. of cortisone after the onset of labor. No further hormonal therapy seemed necessary, and none was given.

CARDIOVASCULAR NEEDLE HOLDER FOR DELICATE SUTURING

Albert P. Giannini, M.D., San Jose, Calif.

During the suturing of blood vessels with 00000 arterial silk on atraumatic needle, it became apparent, especially in deeper wounds, that the ordinary needle holder with the ring-type handle and lock, even when equipped with diamond jaws, was not entirely adequate. The ring-type needle holder on unlatching causes, in most instances, a small amount of movement of the needle while the latter is being released. This motion at times is enough to form small tears at the needle hole. It was noted that the 00000 arterial silk with a swedged-on needle pierced the blood vessels in coarctation, Blalock, Potts, and other cardiovascular procedures with very little force, and when the needle was held in the usual vascular thumb forceps it could easily be pushed through the vessel. The only difficulty was placing and holding the needle in proper position in the thumb forceps.

With the premise that a thumb forceps-type needle holder could work well in this delicate-type suturing and would allow pickup and release of the needle without any movement of the needle, an attempt was made to modify the ends of a regular thumb forceps with diamond jaws to see if that would be satisfactory. However, this was found inadequate as too much thumb pressure was found to be necessary. It was also noted that the usual ring-type diamond jaw needle holder would firmly hold an arterial needle by maintaining thumb pressure but not clamping the holder closed. However, the shape and form of the ring-type needle holder made suturing difficult and hard to control because of the shape of the shanks, the ring handles, and the lack of spring in the shanks.

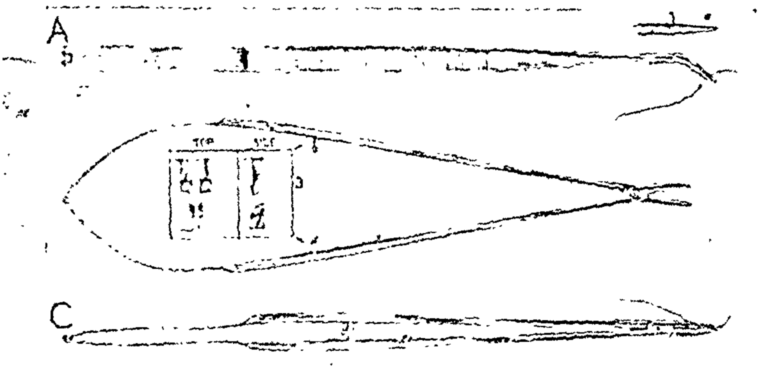
Therefore, the holder shown in the figure was designed. This holder can be used in the thumb forceps position or needle holder position in the hand while suturing. Pickup and release of the needle can be done as a thumb forceps, yet easily holding the needle in any position. This is made possible by the 8:1 mechanical

---

The needle holder used in this study is made with both a straight and angle-type tip and is constructed of stainless steel. It is manufactured by the Lawton Company, 425 Fourth Ave., New York 16.

advantage of shanks to jaws of the holder. The springs were added to the ends of the shanks so that the holder would open with soft, even tension against the fingers. The weight of the holder and the strength of the shanks are such that the needle holder can be held between the fingers in the open position without closing the holder or without the holder slipping out of the fingers with application of little force. The small latch in the center of the needle holder is placed there to keep the holder closed while the nurse places the needle or for any reason should the operator wish to place the needle. While the needle holder is in use the small latch automatically slips through and does not interfere with the use of the needle holder as a thumb forceps.

Hinge 2 in the figure, *A*, is placed there to give the needle holder the adequate amount of stability found necessary for smooth operation of latch 3 in the figure, *B*. The holder may be modified by adding diamond jaws, but these have been found unnecessary, since the needle can be held firmly in any position with its present jaws. The needle can be released and picked up with no unintended movements that may tear a delicate blood vessel while the needle is being released.



Cardiovascular needle holder.

The advantages, therefore, of this needle holder over the usual ring type are: 1. It may be used in the thumb forceps position to suture in difficult areas and to grasp and pull the needle through. 2. It may be used in the regular needle holder position in the hand. 3. It has a smooth pickup and release, obviating unintended movements of the needle. 4. It will hold delicate needles at almost any desired angle. Shown in the figure is the 10-in. model holding 00000 arterial silk on atraumatic needle. Shorter models are also available.

4 Medico-Dental Bldg., Sixth and Santa Clara Streets.

Basic Knowledge.—In the long range, which often but unpredictably turns out to be not very long, practical benefits will also come from advances in basic knowledge. In this area it is important to realize that the possible usefulness of the knowledge to be acquired is an almost irrelevant criterion of the importance of getting it, for the applications of new knowledge are unpredictable and have no bearing upon the incentives or scientific reasoning used by the investigator. But from such advances our whole approach to practical problems may become reoriented by revolutionary new concepts. Here scientific interest motivates the inquiry and curiosity is the guide, but the public interest is deeply involved in the progress made.—Remarks at the Phoenix Memorial Dedication Luncheon, University of Michigan, Ann Arbor, June 9, 1955, prepared by T. H. Johnson, Director of Research, Atomic Energy Commission.

COMPULSORY CASH DISABILITY BENEFITS

This is the first in a series of articles that The Journal *will publish during the next several months concerning the proposal to establish a national system of cash benefits for persons who are totally and permanently disabled. All physicians are urged to acquaint themselves with the facts on this vital issue.*—Ed.

THE LEGISLATIVE BLITZ

The medical profession suddenly is faced by the most serious national legislative crisis to arise since the 1949-1950 attempt to enact a system of national compulsory health insurance. The new problem, cut of the same cloth, has emerged unexpectedly as a result of a legislative blitz in the United States House of Representatives. The House, on July 18, by a roll call vote of 372 to 31, passed H. R. 7225, known as the Social Security Amendments of 1955. The bill was rushed through the House under a procedure suspending the rules, barring amendments, limiting debate to 40 minutes, and requiring a two-thirds vote of approval. Earlier the measure had been sped through the House Ways and Means Committee in executive session without public hearing, despite the protests of Republican committee members who demanded open hearings and careful study of the legislation.

The most controversial provision of H. R. 7225, and the one with the most serious implications for the medical profession, is the section that would make permanently and totally disabled persons at age 50 eligible to receive Social Security benefits not now available to others until age 65. While the American Medical Association, like all thoughtful groups and individuals in the country, has become increasingly concerned over the continued, general expansion of the Social Security system, it takes no position on those proposals that do not involve health or medical care. The Association, however, is specifically opposed to the plan for compulsory cash disability benefits, which would have a direct effect on the medical profession and the future of the American medical care system. Fortunately, the Senate Finance Committee, headed by Sen. Harry Byrd, Virginia Democrat, already has wisely decided to postpone action on H. R. 7225 until the second session of the 84th Congress. At that time there will be extensive public hearings on all aspects of the legislation. This gives the medical profession, and all others interested in these far-reaching Social Security amendments, some five months in which to acquaint themselves with the facts and gird for action.

In addition to the disability benefits, the House bill would lower the retirement age for women from 65 to 62, extend monthly benefits for permanently and totally disabled children beyond the age of 18, and expand compulsory social security coverage to all self-employed professional groups except physicians. Affecting about 1,300,000 persons, the changed benefits will cost an estimated 2 billion dollars a year for the next 20 years and about 2.5 billions annually thereafter. The bill would increase payroll taxes in 1956 by 0.5% each on employers and employees and 0.7% on the self-employed. The same increases would be applied to the already scheduled tax rises in 1960, 1965, 1970, and 1975, bringing the social security tax in 1975 to 4.5% each on employers and employees and 6.75% on the self-employed. The extension of monthly benefits at age 50 to the totally and permanently disabled would apply to an estimated 250,000 persons in the first year and would cost 200 million dollars in benefits, according to the bill's sponsors. In 25 years they predict that one million workers would be receiving disability benefits amounting to 850 million dollars a year. To be eligible for benefits a worker must be at or over age 50, be fully and currently insured under social security, and have 20 quarters of coverage in the last 40 quarters ending with the quarter of disablement.

Benefits would be payable only after a six months' waiting period. The determination of disability would be made by the state agencies that make the determinations under the disability "freeze" provisions enacted last year. The definition of disability is the same as in the freeze provision of present law, except that there would be no presumed disability for the blind. To promote rehabilitation, the bill provides that a person who performs work while under a state rehabilitation program will not, solely by reason of that work, lose his benefits during the first year. The bill also contains a provision that would make it possible to stop the benefits of anyone who, without good cause, refuses available rehabilitation services. The present bill would not provide benefits for the dependents of disabled workers.

The real meaning and future implications of this proposal, as simply another step toward a complete, "cradle-to-grave" social security system, can be seen in some of the remarks made last July 18 in the House debate or published in the Congressional Record for that day. For example, Rep. Dingell of Michigan, perennial advocate of national compulsory health insurance, included the following in a 10-point program for expanding the social security system: "Temporarily disabled persons who are insured on the basis of recent employment before their disability should be eligible for cash benefits for upwards to 26 weeks in a year. Provision should also be made for cushioning the cost of medical services during such period of temporary disability. The disability benefit provisions of H. R. 7225 should be reviewed with a view to reducing or eliminating the requirement that a totally and permanently disabled worker must be age 50 before being eligible for benefits. Consideration should also be given to making benefits available to dependents of insured workers who became totally and permanently disabled."

Rep. Dingell also said: "Another and important amendment which I have been sponsoring over the years, and which will eventually become law, provides 60 days of free hospitalization for all recipients of social security benefits." Numerous members of the House echoed Rep. Dingell's desire for still greater expansion of the social security system. Rep. Zablocki of Wisconsin declared that "the bill before us represents a step in the right direction, and for that reason merits our support." Rep. Fino of New York said that "I will support this bill, not because it goes far enough in humanizing our social security system, but because it represents a step in the right direction. . . . If we are to improve and extend our law, let us go all the way now." And Rep. Roosevelt, also of New York, commented: "It is my candid opinion that such a hearing (public hearings by the House Ways and Means Committee) would have been a farce."

However, a few courageous Congressmen spoke out in protest against the way in which the bill was railroaded through the House, and they urged public hearings and careful study of the legislation. Among them was Rep. Jenkins of Ohio, who said: "I do not, however, believe that our committee has discharged its obligation to either the Congress or to the American people by its brief and closed-door consideration of this vital legislation. I have sought to point out the grave social and economic implications of the bill. I have dwelt at some length upon the staggering ultimate costs of this developing program because I do not believe that either the Congress or the public has any conception of its magnitude.

Rep. Kean of New Jersey had this comment: "By their action in refusing to have public hearings, by their action in turning down my motion to invite insurance actuaries to estimate the cost, by their action in turning down my motion to invite doctors to testify as to possible means of determining disability, the Ways and Means Committee has abdicated its responsibility, and the Senate will write the bill."

Rep. Curtis of Missouri told the House: "All we are engaged in today is making a mockery of the House of Representatives and confirming the mockery already made of itself by the Ways and Means Committee. The Senate leaders have already announced that they intend to hold hearings on this bill. They have already stated that they are not going to abandon, just yet, at any rate, the time-tested procedures that produce good legislation and protect against bad legislation."

The issue will be joined when the second session of the 84th Congress convenes in January and the Senate Finance Committee begins public hearings on the bill. Subsequent articles in this series will outline the American Medical Association's opposition to the disability benefits plan embodied in the legislation and will present the reasons and facts upon which that policy is based.

Our New Chemical Environment.—The mushrooming chemical industry, the incipient wide application of nuclear energy, the revolutionary changes in food processing, and many other recent technologic developments are affecting the urban environment, and consequently the health of man, in multitudinous ways. The numerous benefits associated with these developments have detracted from recognition that the health factor may well be the limiting factor in their continuing development. For example, in the application of nuclear energy for peaceful uses, it is likely that the rate of advancement of such uses will be controlled by the extent to which the radiation health hazards associated with these uses, and with the wastes derived from their uses, can be properly controlled. This limiting condition might some day apply to the chemical industry and to most other new technologic developments. . . . Contamination of sources of water supply, the widespread use of new chemicals in the production and processing of foods, the increasing use of radiopharmaceuticals, of synthetic paints, insecticides, pesticides, detergents, etc., these constitute an extremely complex chemical situation. Today chemicals pervade so many ph [illegible] f man's environment we might say the environment has [illegible] hemicalized."—H. F. Ludwig, F.A.P. ALDOSTERONE AND ALDOSTERONISM

The recent isolation, crystallization, and characterization of aldosterone (11β, 21-dihydroxy, 3,20-diceto-4-pregnen-18-al), a new steroid hormone from the adrenal cortex, has prompted great interest in the role of the hormone in the health and disease.[1] While aldosterone was not isolated until 1952, it had long been ob-
rved that the amorphous fraction of adrenal extracts,
portion remaining after removal of all known crystalline substances, was highly effective in maintaining the life of animals in which adrenalectomy had been done. Identification of the principle or principles responsible for this effect eluded investigators until Grundy and associates, using newly developed methods of chromatography and a sensitive bioassay procedure, succeeded in isolating a highly active substance.[2] Subsequently, in collaboration with their Swiss colleagues Wettstein,
eher, Von Euw, Reichstein, and Schindler, the British
orkers crystallized the active principle and established its chemical structure.[3] They suggested that it be named aldosterone since it differed from corticosterone only in the presence of an aldehyde rather than a methyl group at the C_{18} position. This name has largely replaced the earlier one, electrocortin, bestowed when the physiological action but not the chemical structure of the compound was known. Subsequently, aldosterone was isolated from the adrenal venous blood of dogs and monkeys and from the perfusate of calf adrenals, thus strengthening the concept of the hormonal nature of the compound.

Studies on the biological effects of aldosterone have been limited by the minute amounts of hormone presently available; however, preliminary work indicates the hormone elicits both mineralocorticoid and glucocorticoid effects. Thus, it is at least 20 times as effective as desoxycorticosterone in maintaining electrolyte balance and well-being in patients with adrenal cortical hypofunction and about one-third as active as cortisone i
causing deposition of liver glycogen and in lowering th
eosinophil count in mice in which adrenalectomy ha
been done. Furthermore, secretion of the hormone is a
parently independent or largely independent of the p
tuitary gland but may at least in part be regulated
electrolyte balance.[4]

Elucidation of the relationship of aldosterone and c
tain disease conditions has been greatly advanced
work initiated in 1952 by Luetscher and his associa
on a urinary sodium-retaining substance, since identif
as aldosterone.[5] These investigators found particula
high titers of this substance in the urine of patients suf
ing from certain diseases characterized by edema as
ciated with low sodium excretion, such as nephro
heart failure, and hepatic cirrhosis, while subsequent
vestigators have reported high titers in eclampsia [6]
malignant hypertension.[6b] It is generally conside
however, that the high titers of aldosterone in t
varied conditions are an effect, and not the cause, of
underlying disease process.

Evidence is now accumulating to suggest that
creased aldosterone production may in other insta
actually be the primary cause, rather than a result,
disease condition. Conn [7] has recently described a
tient suffering from intermittent tetany, parasthe
chronic severe muscular weakness, polyuria and
dypsia, and hypertension but with no edema. Labor
studies revealed very high titers of a sodium-reta
substance in the urine, low blood potassium levels,
blood sodium levels, and alkalosis. In addition ther
a renal tubular defect in the reabsorption of
thought to be secondary to chronic hypokalemia.
gery revealed an adrenal cortical adenoma that
found by bioassay to be rich in aldosterone-like ac
After surgery, the patient's clinical symptoms
metabolic abnormalities disappeared, but the latter
be reproduced with small doses of aldosterone.
and Iseri have reported an apparently similar case,
Conn [7] has suggested that certain other reported c

potassium depletion and alkalosis, such as those described by Earle and his associates,[9] by Wyngaarden and his associates,[10] and by Evans and Milne,[11] are also examples of hyperaldosteronism. The report of Evans and Milne is of particular interest since the patient was found to excrete high titers of a sodium-retaining substance in the urine. Conn suggests that these cases represent a hitherto unrecognized clinical syndrome. He has suggested that the name primary aldosteronism be applied to this syndrome to differentiate it from those conditions in which the increased excretion of a sodium-retaining corticoid is apparently secondary to the underlying disease. He further recommends that all patients with an unexplained hypokalemic alkalosis should undergo adrenal surgery, and, even if no adrenal tumor is found, partial or complete adrenalectomy should be considered as a means of combating the metabolic abnormality.

CONTROLS IN WORKMEN'S COMPENSATION

This issue of THE JOURNAL (page 1463) contains an abstract of a much larger collection of data shortly to be issued by the Council on Industrial Health on some monetary aspects of workmen's compensation. The full report will provide committees on workmen's compensation or industrial health in the state medical societies with factual information on trends and distribution of premiums earned and medical and indemnity losses incurred by insured employers in 39 jurisdictions for a 10 year period.

Here is much food for thought. Certain statutory and administrative provisions have long been considered necessary as "controlling factors" in the maintenance of minimal costs for medical care, and indirectly for indemnity. Among a sizable list of such factors several have stood out—the method of physician selection, limitations in medical benefits in time or amount, and fee schedules. This report questions the validity of these concepts. The physician is selected by the employer in 33 jurisdictions in this study. Yet in those jurisdictions where the employee may select the physician, medical losses incurred tend to fall below the median for all in both percentage increases and average ratio of medical to total losses incurred for base periods. In 22 jurisdictions medical benefits are limited or a fee schedule has been set up. Again there appears to be no clear relation between minimal losses incurred and the existence of a "control" measure. Other contributing factors, such as the character of administrative supervision, policies of medical societies, and quality of medical care, should be given due consideration in future discussions of these medical costs. But on the basis of dollar amounts, there is ample evidence that traditional concepts may be in error and that greater flexibility of medical care provisions in workmen's compensation can improve the lot of disabled workers without insuperable economic burdens for anyone.

PROGRESS ON JENKINS-KEOGH BILLS

On July 19 the Committee on Ways and Means of the House of Representatives, by a vote of 16 to 8, included an amended version of the Jenkins-Keogh bills in the "bobtail" revenue bill. In the hectic last days of the first session of the 84th Congress, Chairman Jere Cooper (D., Tenn.) officially killed this catchall revenue bill for this year and stated that the committee will try to complete the bill after Congress reconvenes next January.

This favorable committee vote in July is the high watermark in the long struggle to obtain tax deferment equality for the self-employed and the pensionless employed. During the hearings on the Jenkins-Keogh bills on June 27 and 28, eight congressmen who are not members of the House Ways and Means Committee testified in favor of the principle of these bills. (The testimony presented by the American Bar Association, American Dental Association, American Farm Bureau Federation, American Medical Association, and the statement and analytical report on the bills by the Treasury Department have been published in Bulletin 100 by and may be obtained from the A. M. A. Bureau of Medical Economic Research.) The Secretary of the Treasury thrice granted that the federal revenue laws are unfair to the self-employed and strongly urged that the bills, if approved, exclude the pensionless employed in order to reduce the revenue loss. The bill was so amended. Other changes were the reduction in the maximum amounts that could be excluded annually from $7,500 to $5,000 and in the lifetime maximum from $150,000 to $100,000. Other amendments would permit combinations of an annuity contract with a life insurance policy, with tax deferment only on the annuity part of the premium, and the use of a bank as a custodian of retirement funds. These four amendments were made before the 16 to 8 vote was taken. The failure of the Ways and Means Committee to report out the "bobtail" tax bill before adjournment in August means that the amended Jenkins-Keogh bills cannot be acted upon in the House until the committee approves the completed "bobtail" bill after Congress reconvenes next January. The possibility that the committee will not complete the "bobtail" bill during the next session or will report it out with the amended Jenkins-Keogh bills omitted now seems remote.

The progress made during this first session of the 84th Congress and the strong statements made by many members of Congress during the hearings of June 27 and 28 should encourage physicians, other self-employed persons, and other interested individuals to inform their congressmen of their views while they are at home this fall. The prospects for the enactment of these bipartisan bills to establish a voluntary pension system for the self-employed are definitely on the upgrade. Perhaps the time is approaching when it will no longer be an economic sin to be self-employed.

ORGANIZATION SECTION

PUBLIC RELATIONS INSTITUTE

A public relations meeting combining legislative briefing with informal discussions on medical society public relations activities will be sponsored by the American Medical Association at Chicago's Drake Hotel on Aug. 31 and Sept. 1. Attending this public relations institute will be some 300 representatives of state and county medical societies, woman's auxiliaries, and national medical organizations. On the first day there will be a series of discussion sessions designed to encourage audience participation. Dr. David B. Allman, A. M. A. Trustee and Chairman of the Legislative Committee, will moderate a discussion on the best way to inform the membership of important legislative activity. Other sessions on this morning program are "Planning Ahead Makes for Better PR," "Stimulating PR Interest in the Individual Member," "Magazine Relations: What Do Writers Expect from Doctors," and "Putting A. M. A. PR Aids to Use." Featured in the magazine discussion will be Howard Whitman, author and television commentator, and James Riggs and James Liston, managing editor and articles editor of *Better Homes and Gardens*.

At luncheon on Aug. 31, registrants will hear James E. Bryan, medical public relations consultant. The afternoon session will consist of three separate group discussions taking up the special public relations problems of state medical societies, large county societies, and small county societies. The second day of the institute will be made up of briefing sessions. First, registrants will hear about new national public relations projects needing cooperation of state and county societies. Then the group will learn details on the new social security issue pending in Congress. After presentation of A. L. Kirkpatrick, manager, insurance department, Chamber of Commerce of the United States, Dr. Ernest B. Howard, A. M. A. Assistant Secretary, will moderate a panel discussion on "What Social Security Expansion Means to the Medical Profession." As part of the luncheon session on Sept. 1, the institute audience will get advance information on forthcoming network television programs of special interest to the medical profession. Plans for a new weekly series of telecasts entitled "Medical Horizons" will be outlined; Jim Moser, creator of the "Medic" program, will personally describe the 1955-1956 blueprint for the popular NBC series, and details on the fall and winter schedule of "March of Medicine" will be revealed.

Winding up the 1955 Public Relations Institute will be the showing of films. A new "Medic" show will be previewed, and registrants will have an opportunity to see A. M. A. motion pictures available for showing on television or to club, church, and school audiences. Throughout the two-day meeting, a display of state and county society public relations projects and exhibits obtainable on loan from the A. M. A. will be on view in an adjoining room.

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Tax Postponement for Self-Employed

Congressman Lipscomb (R., Calif.) has introduced, in H. R. 5605, a measure to encourage the establishment of voluntary pension plans by individuals. He proposes to postpone taxes on limited amounts of the taxpayers' net income if such sums are used in setting up a restricted retirement annuity. This measure is identical with H. R. 9 and 10 by Congressman Jenkins (R., Ohio) and Keogh (D., N. Y.), and similar to H. R. 2092 by Congressman Ray (R., N. Y.). This bill was referred to the Committee on Ways and Means.

Assistance to States for Industrial Safety

Congressman Frelinghuysen (R., N. J.), in H. R. 5740, has introduced a measure identical to S. 1091 and similar to H. R. 4877, reported in The Journal, May 14, 1955, page 125. This would give assistance to the states for improving and maintaining safe work places and practices in industry. This bill was referred to the Committee on Education and Labor.

Water Pollution Control Act

Congressman Johnson (D., Wis.) would extend and strengthen the Water Pollution Control Act of 1948 by H. R. 5897, which is similar to S. 890, H. R. 3426, H. R. 5296, and H. R. 5369, reported in The Journal, June 4, 1955, page 407. The Johnson measure however provides the addition of a new section to permit incentive grants and loans at 2% to expedite the construction of sewage treatment plants. This bill was referred to the Committee on Public Works.

Appropriation for the World Health Organization

Representative Carnahan (D., Mo.), in H. J. Res. 293, and Senator Humphrey (D., Minn.), in S. J. Res. 78, would increase from 3 million to 5 million dollars the limit on the United States annual obligation to the World Health Organization. Congressman Judd (R., Minn.), in H. J. Res. 304, would make a similar report on the limit in U. S. obligation, but the total appropriation could not exceed 33.3% of WHO's total operating budget. Both House measures were reported to the Foreign Affairs Committee. The Humphrey bill was referred to the Committee on Foreign Relations.

Doctor-Draft Extension, Military Scholarships, and Equalization Pay

Congressman Vinson, in H. R. 5946, introduced the committee's version of the "Doctor-Draft" act extension, the military medical scholarship bill, and the $100 per month equalization pay for medical officers. Title 1 would extend the "Doctor-Draft" law until July 1, 1957, and provide further that "Effective July 1, 1955, and notwithstanding any other provision of this subsection, no person who after attaining the thirty-fifth anniversary of the date of his birth shall be liable for induction under this subsection if he has applied for a commission in one of the Armed Forces and was rejected for such commission on the sole ground of a physical disqualification." This included the simple extension of the doctor draft provided in H. R. 2886 (reported in The Journal, March 19, 1955, page 1028). Title 2 would provide for the establishment of medical and dental scholarships similar to Congressman Bennett's (D., Fla.) measure, H. R. 4645, and the Senate bill S. 1444 introduced by Senators Russell (D., Ga.) and Saltonstall (R., Mass.), which were reported in The Journal, June 11, 1955, page 483. Title 3 would continue the $100 special pay for physicians, dentists, and veterinarians.

Senator Russell, in S. 1946, introduced the administration's $100 equalization pay bill for physicians, dentists, and veterinarians but would require physicians obligated under the basic Selective Service Act to serve an additional year if they were to receive the $100 pay incentive. This was abandoned for the House version, H. R. 6057, subsequently H. R. 3005. Congressman Vinson introduced, in H. R. 6057, a measure to replace H. R. 5946, the essential difference being that the section on medical scholarships was deleted. This measure, H. R. 6057, was reported favorably to the House. In the Senate, hearings were held on H. R. 6057, and it was attached to H. R. 3005, the extension of the basic Selective Service Act and the benefits under the Dependent's Assistance Act. As approved by the committee, a veterinarian if employed by the Department of Agriculture for 24 months would not be liable for induction. This provision was eliminated in the conference between the House and the Senate and the upper limits of the draft law dropped from 51 to 46. These bills were handled by the respective armed services committees.

Commission on Aging and Aged

Congressman Corbett (R., Pa.) has introduced, in H. R. 6044 a measure identical to S. 693 and similar to a number of previously reported measures that would study problems of the aging and the aged and make recommendations to Congress This bill was referred to the Committee on Education and Labor

MEDICAL NEWS

CALIFORNIA

Cerebral Palsy Training Program.—The first term of the training course for personnel concerned with the care of cerebral-palsied children for the academic year 1955-1956 begins at Children's Hospital in San Francisco Sept. 1. The program, supported by the United Cerebral Palsy associations in the hospital, provides training in the care of the cerebral-palsied preschool child; seminars and conferences; and contacts with parents of the palsied children in the school through home visits and with the public and private agencies concerned. The curriculum is set up to train occupational therapists, physical therapists, and nursery school teachers who wish to specialize in the cerebral palsy field. For information write to: Dr. Luigi Luzzatti, Children's Hospital, 3700 California St., San Francisco.

COLORADO

State Medical Meeting in Denver.—The 85th annual session of the Colorado State Medical Society will convene at the Shirley-Savoy Hotel, Denver, Sept. 20-23, under the presidency of Dr. Samuel P. Newman, Denver. Guest speakers and their first presentations will include:

L. Henry Garland, San Francisco, Radiologic Diagnosis of Certain Pelvic Disorders.
John C. Burch, Nashville, Tenn., Diagnosis of Pelvic Masses.
Philip D. Wilson, New York, Differential Diagnosis of Low Back Pain.
Charles A. Ragan, New York, Rheumatoid Arthritis.
James T. Priestley, Rochester, Minn., Tumors of the Adrenal Cortex.
Thomas L. Shipman, Los Alamos, N. Mex., Control of the Most Dangerous Element Known to Man.

On Wednesday at 12:10 p. m. Dr. Warren W. Tucker, Denver, will serve as moderator for a symposium on the pelvis by Drs. Burch, Wilson, and Garland. At the same time on Thursday Dr. Harry C. Hughes, Denver, will be moderator of a symposium on the joints, presented by Drs. Wilson, Ragan, and Garland. Friday noon Drs. Priestley and Ragan will present a symposium on the adrenals, of which the moderator will be Dr. Carl S. Gydesen, Colorado Springs. Through the cooperation of Wyeth Laboratories, closed-circuit telecasts on the subjects of the symposiums will originate daily from the Denver General Hospital about two hours preceding the presentation of the symposiums. Social events will include a dinner Tuesday, 6:30 p. m., followed by a stag smoker, and the annual banquet Thursday, 6:30 p. m., sponsored by the woman's auxiliary, which will meet simultaneously. Tuesday afternoon the golf tournament will be held at the Wellshire Country Club and the Trap Shoot at the Denver Municipal Trap Club. There will be a handicap state medical bowling meet.

FLORIDA

Society News.—Newly elected officers of the Florida Academy of General Practice include: Dr. Frank T. Linz, Tampa, president; Dr. Leo M. Wachtel, Jacksonville, president-elect; Dr. Leon S. Eisenman, Hialeah, vice-president; and Dr. James B. Hodge, Tampa, secretary-treasurer.

Appoint Professor of Medicine.—Dr. Ralph Jones Jr., formerly director of C. W. Robinson section, department of medicine, Hospital of the University of Pennsylvania, has been appointed chairman of the department of medicine, University of Miami School of Medicine, Coral Gables. He succeeds Dr. Franz H. Stewart, who accepted the appointment on a pro tem basis for one year only and who now returns to full-time private practice. Dr. Jones was recently named chairman of the national coordinating panel for work on cancer chemotherapy. After service in the Medical Corps of the U. S. Army, he was a research associate in medicine and a research associate in urology at the University of Chicago School of Medicine.

ILLINOIS

Dr. Fischer Honored.—Dr. Andrew L. Fischer, Hoffman, was honored for 50 years of active practice at the Clinton County Medical Society dinner meeting June 8 at St. Joseph's Hospital in Breese. Dr. Fischer has been a company physician and surgeon of the Southern Railway System since 1915. He was present at the dedication of St. Mary's Hospital in Centralia in 1908, is the only physician of the original hospital staff using its facilities, and is the oldest physician now using the hospital. During World War I Dr. Fischer served in the Army Medical Reserve Corps. In World War II he received honorable mention for distinguished service as a selective service medical examiner.

Chicago

Research Grants.—The Hektoen Institute for Medical Research of the Cook County Hospital announces receipt of $10,000 from the Damon Runyon Memorial Fund for Cancer Research for studies in leukemia; $10,000 from the Dr. Leonard H. and Louis Weissmann Medical Research Foundation for studies in radioactive isotopes; and $15,000 from the Olivia Sue Dvore Foundation for leukemia research.

New Head of Physical Medicine Department.—Dr. David I. Abramson, who has been affiliated with the University of Illinois College of Medicine since 1946, will become head of the department of physical medicine and rehabilitation Sept. 1 at the University of Illinois Research and Educational Hospitals. Dr. Abramson, an attending physician at Michael Reese, Mt. Sinai, and Hines Veterans Administration hospitals, is also a consultant in peripheral vascular diseases for the regional office of the Veterans Administration. He formerly taught at the University of Cincinnati and directed cardiovascular research at May Institute for Medical Research in Cincinnati. A medical officer in the U. S. Army from 1942 to 1946, he was discharged with the rank of major.

MARYLAND

Dean Wylie Retires.—Dr. Hamilton Boyd Wylie, dean, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, retired July 1 after 42 years of service. Dean Wylie, who began his career at the school of medicine in 1913 as an associate in physiological chemistry, became assistant dean in 1942, acting dean in 1946, and later dean of the school of medicine. Dr. Wylie was honored on his birthday, when May 3 was designated by the university's medical library as "Wylie Day." A display including photographs and articles concerning Dean Wylie was on view in the library's reading room, and an informal reception was held during the late afternoon.

Personal.—Dr. George Washington Corner, Baltimore, director of the department of embryology, Carnegie Institution, received the honorary doctor of laws degree from Tulane University of Louisiana, New Orleans, at commencement May 31.——Dr. John C. Whitehorn, Henry Phipps Professor of Psychiatry and director of the department of psychiatry at Johns Hopkins University School of Medicine and psychiatrist-in-chief of the Johns Hopkins Hospital, Baltimore, since 1941, received an honorary doctor of science degree at the University of Nebraska Aug. 5. Dr. Whitehorn, who was previously affiliated with the Massachusetts General Hospital and Harvard Medical School, Boston, and Washington University School of Medicine, St. Louis, served as president of the American Board of Psychiatry and Neurology in 1946 and of the American Psychiatric Association in 1951.

MASSACHUSETTS

Nursing Course in Poliomyelitis.—Boston University is conducting a course on "Poliomyelitis Nursing" to train graduate nurses in administration, teaching, and supervision for poliomyelitis units. During the morning the seven nurses, who have come from Puerto Rico, Michigan, and Oklahoma, as well as New England,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

work in the poliomyelitis wards at Children's Medical Center. In the afternoons, classes are held. Two weeks of the six week course will be spent at the Wellesley Respirator Center, a part of the Children's Medical Center.

Dr. Drinker Honored.—The portrait of Dr. Cecil Kent Drinker was recently unveiled in the Henry Pickering Bowditch Library of Harvard Medical School, Boston. Dr. Drinker's association with Harvard University began in 1916, when he was instructor in physiology. He served as professor of physiology in 1923 and as head of the department in the school of public health from its beginning until 1947. He also served as assistant dean of the school of public health from 1924 to 1935 and as dean from 1935 to 1942. Among the speakers at the ceremony were Dr. James L. Gamble, professor emeritus of pediatrics; Dr. J. Howard Means, Jackson Professor Emeritus of Clinical Medicine; Dr. George Packer Berry, dean of Harvard Medical School; and Dr. Eugene M. Landis, Higginson Professor of Physiology, who presented Dr. Drinker with a book of letters and telegrams from former students and friends who were unable to attend the ceremony.

MINNESOTA

University News.—The University of Minnesota Medical School, Minneapolis, recently established a separate department of anesthesiology, formerly a segment of the department of surgery. The head of the new department is Dr. Frederick H. Van Bergen.

Symposium on Arteriosclerosis.—The Minnesota Symposium on Arteriosclerosis, sponsored by the University of Minnesota and the Minnesota Heart Association, will be held at the Mayo Memorial in Minneapolis Sept. 7-9. General sessions and a half day of clinic and laboratory visits will be devoted to five major topics: "The Challenge of Arteriosclerosis," "Atherosclerosis," "Peripheral and Cerebral Arteriosclerosis," "The Internist and Some Tools," and "The Surgical Treatment of Arteriosclerosis." Principal speaker at the Wednesday dinner meeting in the Minneapolis Club will be Dr. Paul Dudley White, Boston, who will discuss "The Coronaries Through the Ages." Other participants include: Drs. E. Cowles Andrus, Baltimore, Irvine H. Page, Cleveland, Louis N. Katz, Chicago, and James Watt, Bethesda, Md. General chairman of the symposium is Ancel B. Keys, Ph.D., of the University of Minnesota. For information, write Dr. Robert B. Howard, Mayo Memorial, University of Minnesota, Minneapolis 14.

NEW MEXICO

Indian Health Area Office.—Dr. Henry W. Kassel, a commissioned officer in the U. S. Public Health Service, has been appointed medical officer in charge of the Indian health area office in Albuquerque, Surgeon General Scheele of the U. S. Public Health Service has announced. Dr. Kassel, who will take over his new duties Sept. 1, will be responsible for medical care and public health services to more than 101,000 Indians on reservations located in four states. The Albuquerque area office has jurisdiction over medical care and health in the following Indian agencies: Navajo in New Mexico, Arizona, and Utah; Consolidated Ute in Colorado; and United Pueblo, Jicarilla Apache, Mescalero Apache, and Zuni in New Mexico. The area office also is responsible for the practical nursing school and sanatorium for Indians at Albuquerque. Since January, 1950, Dr. Kassel has been assigned to the Denver regional office of the U. S. Department of Health, Education, and Welfare, working with state health departments in Montana, Colorado, Idaho, Wyoming, and Utah. He was chronic disease consultant for this region until October, 1951, when he became chief of medical programs for the region.

NEW YORK

Lecture on Endometriosis.—Dr. Carl T. Javert, professor of gynecology and obstetrics, Cornell University Medical College, New York City, will speak on endometriosis at 8:30 p. m., Sept. 8, at the Jewish Chronic Disease Hospital, East 49th Street and Rutland Road, Brooklyn.

Rehabilitation of the Blind.—A program of professional training in rehabilitation of the blind, presented at the Industrial Home for the Blind, will offer a 20 week course for workers entering the following areas of specialization: rehabilitation counselor; vocational guidance director; vocational instructor; psychologist; physical orientation and foot travel instructor; placement specialist; service stands supervisor; vocational program administrator; and specialist in work for the deaf-blind. There is no tuition fee. A small number of traineeships ($50 a week) are available. They are intended to cover room, board, and incidental expenses. These are meant for students whose residence is outside of the New York City area. Closing date for applications for the first program is Aug. 29. Two 20 week programs are scheduled for the academic year 1955-1956: Program 1, Sept. 19, 1955, through Feb. 3, 1956, and Program 2, Feb. 13 through June 29. For information write Mr. Winfield S. Rumsey, Director of Project, Industrial Home for the Blind, 57 Willoughby St., Brooklyn 1.

Personal.—Dr. Cewsme S. Barresi, Silver Creek, was honored recently when a dormitory at Alfred University was named for him.——Luther E. Woodward, Ph.D., senior community mental health representative of the New York State Department of Mental Hygiene, has received the annual Norma and Murray Hearn Social Action award for his "pioneer work in the field of mental health."——At the 97th commencement of the State University of New York College of Medicine at New York City, Brooklyn, the eighth Alumni Medallion for Distinguished Service to American Medicine was presented to Dr. Alexander S. Wiener for his basic work in the genetics of the blood groups, for allergic disorders, and for his contributions to transfusion reactions and exchange transfusions.——Dr. Hyman Pleasure, assistant director at the Edgewood Division of Pilgrim State Hospital in Brentwood, has been appointed director of Middletown State Homeopathic Hospital, succeeding Dr. Walter A. Schmitz, who retired as director on July 31 after 41 years on the staff of the hospital.——Dr. F. Adrian Kantrowitz, instructor in surgery at New York Medical College, Flower and Fifth Avenue Hospitals, New York City, has been named to concurrent posts in Brooklyn at the State University of New York College of Medicine at New York City and Maimonides Hospital, where he will be assistant professor of surgery in charge of the cardiovascular surgery department.

New York City

Name Professor of Ophthalmology.—Dr. Conrad Berens, recently appointed life member of the Harvey Society, has been promoted from associate professor to professor of ophthalmology at New York University Post-Graduate Medical School. Dr. Berens is ophthalmic surgeon, pathologist, and director of research at the New York Eye and Ear Infirmary; director of ophthalmology at Midtown Hospital; and director surgeon of the Seamen's Church Institute.

Mental Hygiene Clinic for the Deaf.—The Office of Vocational Rehabilitation of the U. S. Department of Health, Education, and Welfare recently announced an initial grant of $27,800 to the New York State Psychiatric Institute to establish and conduct a mental hygiene clinic for the deaf. The clinic, which will be located at the Psychiatric Institute, 722 W. 168th St., will serve the deaf in three major areas: (1) in research activities, (2) in counseling and therapeutic services, and (3) in training of professional workers—psychiatrists, psychologists, social workers, and others. Dr. Franz Josef Kallmann, professor of psychiatry at Columbia University College of Physicians and Surgeons and head of the department of medical genetics at the New York State Psychiatric Institute, will direct the clinic.

OHIO

Alvarenga Prize to Dr. Rammelkamp.—On July 14 the College of Physicians of Philadelphia awarded the Alvarenga prize for 1955 to Dr. Charles H. Rammelkamp, Cleveland, "for his outstanding work in the field of streptococcic infections, particularly in relation to rheumatic fever and nephritis." The prize was established by the will of Pedro Francisco DaCosta Alvarenga of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the college on the anniversary of the death of the testator in 1883.

Course on Forensic Medicine.—The Law-Medicine Center of Western Reserve University, Cleveland, will present a course, "Law-Medicine Problems," on 15 Tuesday evenings from 7 to 9 p. m., starting Sept. 20, at the WRU School of Law, 2145 Adelbert Rd. Six lectures will concern diseases and injuries of the heart and vascular system, and seven sessions will deal with injuries and diseases of the head and spinal cord. This noncredit course (tuition, $55) is planned for physicians, attorneys, claimsmen, industrial relations personnel, labor union officers, and others dealing with medicolegal problems. Information is available by writing to: Director, Law-Medicine Center, Western Reserve University, Cleveland 6.

PENNSYLVANIA

State Medical Meeting in Pittsburgh.—The 105th annual session of the Medical Society of the State of Pennsylvania will convene at the Hotel William Penn, Pittsburgh, Sept. 20-23, under the presidency of Dr. Dudley P. Walker, Bethlehem. The general sessions will open Tuesday at 1 p. m. with the following program:

Investment Planning for the Physician, Mr. Malcolm E. Lambing, Pittsburgh.
Insurance, Mr. George H. Hafer, Harrisburg.
The Doctor and His Income Tax, Mr. George E. Guentner, Pittsburgh.
The Doctor and His Office, Mr. James E. Bryan, Summit, N. J.

At 3:30 p. m. Dr. Isidor S. Ravdin, Philadelphia, will serve as moderator for "The Care of Casualties in Major Catastrophes," in which the first paper, "How to Reduce Mortality" by Dr. Walker, will be followed by "Plasma Transfusions in Hypovolemic Shock and Malnutrition" by Dr. J. Garrott Allen, Chicago; "Preservation of Blood by Freezing" by Lieut. Col. William H. Crosby, Washington, D. C.; "Lessons Learned in a Mobile Surgical Hospital and Their Application in the Care of Mass Casualty Disaster" by Lieut. Col. Kryder E. Van Buskirk, Washington, D. C.; and "What Is My Responsibility as a Practicing Surgeon?" by Dr. William T. Fitts Jr., Philadelphia. Wednesday morning Dr. John W. Shirer, Pittsburgh, will moderate the program, "Present Status of Health and Welfare Plans," which will open with a paper, "Problems Encountered in the Operation of the United Mine Workers of America Welfare and Retirement Fund" by Dr. Warren F. Draper, executive medical officer, United Mine Workers of America, Washington, D. C. Dr. Joseph A. Langbord, medical director, Sidney Hillman Medical Center, Philadelphia, will speak for the Amalgamated Clothing Workers Health and Welfare Plan and Mr. John F. Tomayko, insurance and pension department, United Steelworkers of America, Pittsburgh, for the United Steelworkers of America Health and Welfare Plan. Thursday morning will be devoted to consideration of the following problems created by new developments in medicine:

The Cortisone and ACTH Story, Thaddeus S. Danowski, Pittsburgh.
Endocrine Aspects for Control of Neoplastic Disease, Rulon W. Rawson, New York.
The Diabetic Problem, George E. Anderson, Brooklyn, N. Y.
Hypertensive Drugs, Charles C. Wolferth, Philadelphia.
Progress in Poliomyelitis, Jonas E. Salk, Pittsburgh.
Short and Long-Term Anticoagulant Therapy in Coronary Artery Disease, Thomas M. Durant, Philadelphia.

School health problems will be discussed Thursday afternoon by Drs. Thomas E. Shaffer, Columbus, Ohio, and Carl C. Fischer, Philadelphia. Dr. Earl D. Osborne, Buffalo, will open the meeting on industrial dermatitis, presented by the section on dermatology, with "A Therapeutic Armamentarium for the Treatment of Skin Diseases in Industrial Medical Practice." The section on surgery will have as its first speaker Dr. Harris B. Shumacker Jr., Indianapolis, who will consider surgery of the great blood vessels. Dr. Martin Cherkasky, New York, will discuss "Practical Solutions" at the end of the program on chronic illness problems and solutions, presented Thursday afternoon by the section on preventive medicine and public health. "Physical Medicine and Rehabilitation—Its Significance and Relationship to Other Specialties in Medicine" will be discussed by Dr. Frank H. Krusen, Rochester, Minn., Thursday afternoon before the section on physical medicine and rehabilitation.

Philadelphia

Dr. Esmond Long Retires.—Dr. Esmond R. Long, director of medical research for the National Tuberculosis Association and director of the Henry Phipps Institute for the Study, Prevention, and Treatment of Tuberculosis of the University of Pennsylvania, retired from these positions July 1 to devote his time to research and writing. Three years ago Dr. Long resigned as executive secretary of the American Trudeau Society and as editor-in-chief of the *American Review of Tuberculosis and Pulmonary Diseases.* A prolific writer, he is the author of more than 250 papers and articles as well as "A History of Pathology," published in 1928, and "The Chemistry of Tuberculosis," in which he collaborated with Dr. H. Gideon Wells. Dr. and Mrs. Long plan to make their home in Pedlar Mills, Va.

Personal.—Dr. Harry E. Bacon was recently made an honorary fellow of the Japanese College of Surgeons and the Chiba Surgical Society.——Dr. Philip R. Trommer, associate in medicine at Woman's Medical College of Pennsylvania, has been elected president of the Eastern Pennsylvania chapter of the Arthritis and Rheumatism Foundation at the annual meeting.——At its annual meeting in Los Angeles, the American Urological Association awarded first prize to Dr. William C. Shoemaker, a resident surgeon at Hahnemann Medical College and Hospital, for his essay, "Reversed Seromuscular Grafts in Urinary Tract Reconstruction."——Dr. Mollie A. Geiss, professor of pathology, Woman's Medical College of Pennsylvania, has resigned after 33 years of service on the faculty. She will be succeeded by Dr. Isadore N. Dubin, presently with the Armed Forces Institute of Pathology, Washington, D. C., as chief of the hepatic pathology section.——Dr. Carl F. Schmidt, professor of pharmacology, University of Pennsylvania School of Medicine, lectured at the National Defense Medical Center in Formosa during July, under the auspices of the American Bureau for Medical Aid to China, of which he is a director. The bureau gives assistance to the National Defense Medical Center through provision of fellowships, equipment, and medical journals. Dr. Schmidt is past-president of the American Society of Pharmacology.——Dr. Gilbert B. Meyers, medical supervisor of the Philadelphia plant of the Electric Storage Battery Company, received a certificate for outstanding work in industrial medicine at the annual meeting of the Industrial Medical Association in Buffalo April 27. Under Dr. Meyer's leadership a control program at the Electric Storage Battery Company's plant is reported to have virtually eliminated loss of industrial working time due to lead exposure.

RHODE ISLAND

Fiske Fund Contest.—The trustees of the Fiske Fund of the Rhode Island Medical Society will award $350 for the best dissertation worthy of recompense on the subject "Use of Radio-Active Isotope in the Treatment and Investigation of Disease." Entries should be sent to Secretary to the Trustees, John E. Farrell, Sc.D., 106 Francis St., Providence 3, on or before Feb. 2, 1956, with a motto inscribed, and should be accompanied by a sealed envelope bearing the same motto on the outside and the sender's name and address within. Manuscripts must be typewritten, double-spaced on standard typewriter paper, and should not exceed 10,000 words.

SOUTH CAROLINA

Anniversary Issue.—The *Journal of the South Carolina Medical Association* for June is the 50th anniversary number. In addition to articles on medical progress in various fields, it contains a history of medical journalism in South Carolina by Dr. Joseph I. Waring, Charleston.

SOUTH DAKOTA

State Medical Election.—Newly elected officers of the South Dakota State Medical Association include: Dr. F. Daniels Gillis Sr., Mitchell, president; Dr. Alonzo P. Peeke, Volga, president-elect; Dr. Michael M. Morrissey, Pierre, vice-president; and Dr. Arthur P. Reding, Marion, secretary-treasurer.

TENNESSEE

Society News.—Newly elected officers of the Tennessee Radiological Society include: Dr. John M. Wilson, Memphis, president; Dr. Ben R. Mayes, Nashville, vice-president; and Dr. George K. Henshall, Chattanooga, secretary-treasurer.

Cardiovascular Lectureship.—The Memphis Heart Association has established an annual cardiovascular lectureship at the University of Tennessee College of Medicine, Memphis. The guest lecturer, to be paid by the association and selected by representatives of the association and the university, will lecture in the fall as a part of the teaching program for medical students. Members of the staff of John Gaston Hospital and Memphis physicians will be invited to attend. The lectureship will pertain to the broad field of cardiovascular problems.

TEXAS

Portrait of Dr. Cary.—A portrait of the late Dr. Edward H. Cary, 85th President of the American Medical Association and president and founder of the Southwestern Medical Foundation, was recently hung in the conference room of the new permanent headquarters of the foundation in the Medical Arts Building, Dallas. The portrait by Dmitri Vail was commissioned by *The Times Herald.*

Fiftieth Anniversary Number.—The July issue of the *Texas State Journal of Medicine* commemorates the 50th anniversary of that periodical. It contains an article on medical and surgical progress from 1905 to 1955 by Dr. Thomas H. Thomason, Fort Worth, and "Medicine in an Industrial Civilization" by Dr. Walter B. Martin, Norfolk, Va., immediate past-president of he A. M. A. This paper was read by Dr. Martin at the annual session of the Texas Medical Association April 25.

WASHINGTON

Blood Vessel Bank.—The Washington State Heart Association has established a blood vessel bank that will provide blood vessels free of charge to physicians. Should a suitable donor become available somewhere in the state, information pertinent to procurement, preservation, and storage may be obtained by contacting Drs. Allan W. Lobb, Dean K. Crystal, or Clyde L. Wagner, in Seattle, at 1110 Harvard Ave. (Ca. 3663), or by calling the association. Requests for grafts should be directed o the same places.

WEST VIRGINIA

Society News.—The recently organized West Virginia Pediatric Society held its first scientific meeting at the Daniel Boone Hotel, Charleston, April 15. Among the out-of-state speakers were Drs. Frank Burke, Washington, D. C.; Samuel Livingston, Baltimore; and James B. Arey, Philadelphia. Officers of the society are: Dr. Thomas G. Potterfield, Charleston, president; Dr. Warren D. Leslie, Wheeling, vice-president; and Dr. Helen B. Fraser, Charleston, secretary-treasurer.

Degree in Speech Correction.—The department of speech of West Virginia University, Morgantown, has been authorized by the graduate school of the university to offer a course of study leading to the master of science degree in speech correction and audiology. Students holding a baccalaureate degree who do not have the undergraduate hours in speech presently required for entrance to the master of arts program in speech will be admitted to the course. The curriculum established for the achievement of the degree includes basic and advanced courses in speech correction, pathology, audiology, and psychology, plus supervised clinical experience. Information may be obtained by writing the Head, Department of Speech, West Virginia University, Morgantown.

ALASKA

Medical Election.—Newly elected officers of the Alaska Territorial Medical Association include Dr. Milo H. Fritz, Anchorage, president; Dr. Louis A. Salazar, Ketchikan, first vice-president; Dr. Hugh B. Fate, Fairbanks, second vice-president; and Dr. Robert B. Wilkins, Anchorage, secretary-treasurer.

GENERAL

New Publication on Criminal Psychodynamics.—Dr. Benjamin Karpman of Saint Elizabeths Hospital, Washington 20, D. C., is editor of the *Archives of Criminal Psychodynamics,* a cooperative enterprise devoted to the encouragement of research in the field of criminal behavior. Volume 1 contains the editor's article, "Criminal Psychodynamics: A Platform." Manuscripts and correspondence should be addressed to the editor.

Medical Electronics Sessions.—Two medical electronics sessions will be held during the meeting of the West Coast Institute of Radio Engineers in San Francisco Aug. 24-26. On Thursday a medical and engineering symposium on instrumentation will be held at 7:30 p. m. in room 301 at the civic auditorium. Participants will include Drs. Sydney F. Thomas, Palo Alto (Calif.) Clinic; Herbert N. Hultgren, Stanford University Hospital, San Francisco; and Tracy Jackson Putnam, Cedars of Lebanon Hospital, Los Angeles. There is no registration fee for either event. Members of the medical profession are invited.

Meeting on Physical Medicine.—The American Congress of Physical Medicine and Rehabilitation will hold its 33rd annual scientific and clinical session at the Hotel Statler, Detroit, Aug. 28-Sept. 2. The presidential address will be delivered Tuesday at 2 p. m. by Dr. William D. Paul, Iowa City, after which the following symposium on rehabilitation of injured workers will be moderated by Dr. Howard A. Rusk, New York:

Mobilization Schedule of Common Fractures, C. Leslie Mitchell, Detroit.
The Amputee in Industry—A Follow-Up Study, Charles Long II, Detroit.
Testing and Training Work Capacity, Bruce H. Young, Malton, Ontario, Canada.
The Industrial Physician in Rehabilitation, Earle A. Irvin, Detroit.
Management's Problems in Placement of Handicapped Workers, Mr. Earl R. Bramblett, Detroit.
Role of the Federal Government in Vocational Rehabilitation, Miss Mary Switzer, Washington, D. C.

Wednesday at 9 a. m. Dr. Jacob Meislin, Montrose, N. Y., will moderate a symposium, "Contribution of Psychiatry to Physical Medicine and Rehabilitation," in which the participants will be Dr. William Benham Snow, New York, Dr. A. Ray Dawson, Richmond, Va., and (by invitation) Drs. John C. Nemiah, Boston, and Saul H. Fisher, New York. The Wednesday afternoon session will be devoted to a symposium on rehabilitation centers, including six presentations by invitation. Dr. Ralph E. DeForest, Secretary, and Dr. Frederic T. Jung, Assistant Secretary and Director of Physical Laboratory, A. M. A. Council on Physical Medicine and Rehabilitation, Chicago, will serve as discussants for papers to be presented during the opening general scientific session Tuesday morning. The fifth John Stanley Coulter Memorial Lecture is scheduled for Thursday at 2 p. m. (speaker to be announced).

Society News.—Newly elected officers of the **American Society for Pharmacology and Experimental Therapeutics** include: Dr. Harry Beckman, Milwaukee, president-elect; Dr. Carl C. Pfeiffer, Emory University, Ga., secretary; and Dr. James M. Dille, Seattle, treasurer.——Officers of the **Association of Food and Drug Officials of the United States** for 1955-1956 include: Mr. Eugene H. Holeman, Nashville, Tenn., president; Mr. James M. Doughty Jr., Santa Fe, N. Mex., vice-president; and Mr. Evan Wright, Topeka, Kan., secretary-treasurer.——The **Western Industrial Medical Association** recently elected the following Los Angeles physicians: Packard Thurber Jr., president; Douglas D. McKinnon, vice-president; Edward J. Zaik, secretary; and Clarence L. Lloyd, treasurer.——Newly elected officers of the **National Tuberculosis Association** include: Mr. Edward T. Fagan, Brooklyn, N. Y., president; Dr. Howard W. Bosworth, Los Angeles, president-elect; Dr. John D. Steele, Milwaukee, and Mr. Peter W. James, Des Moines, vice-presidents; Mrs. Morrell De Reign, Caruthersville, Mo., secretary; and Collier Platt, New York, treasurer.——Newly elected officers of the **American Therapeutic Society** include: Dr. Fred E. Ball, Chicago, president; Drs. Gerald H. Pratt, New York, Robert J. Coffey, Washington, D. C., and L. Clagett Beck, Honolulu, Hawaii, first, second, and third vice-presidents respectively; Dr. Oscar B. Hunter Jr., Washington, D. C., secretary; and Dr. Joseph A. Davis, Chicago, treasurer.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

FOREIGN

Poliomyelitis Program in Israel.—According to the *Hadassah Newsletter*, published by the Women's Zionist Organization of America, poliomyelitis, which previously had been negligible, in 1950 affected 1,604 children in Israel, paralyzing over 80%. This was a rate of 14.5 cases per 10,000 population, whereas the average annual incidence in the United States was 2 to 3 cases per 10,000 persons. Since 1950 there have been about 800 new cases in Israel every summer, an incidence of 5 per 10,000 (taking into account the increase in population), or twice the rate of the United States. Whereas, in America, children of the first grades in school are the most affected, in Israel almost all the sufferers are infants, 79% of all the afflicted children being under 3 years of age and 92% under 5 years. In Jerusalem, where a severe outbreak occurred in 1953 (220 cases were reported among a population of 150,000), the acute cases are cared for in the special isolation station of the Shaare Zedek Hospital. Severely handicapped children are admitted as in-patients to the Hospital for Crippled Children in Jerusalem. The Hebrew University-Hadassah Medical School virus research laboratory recently received a research grant from the World Health Organization and was named the WHO Regional Polio Research Laboratory for the Eastern Mediterranean.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

American Medical Association Public Relations Institute, Drake Hotel, Chicago, Aug. 31- Sept. 1. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

Academy of Psychosomatic Medicine, Hotel Plaza, New York, Oct. 6-8. Dr. Ethan Allan Brown, 75 Bay State Road, Boston 15, Secretary.

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 3-6. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Executive Secretary.

American Association of Medical Record Librarians, LaSalle Hotel, Chicago, Oct. 3-7. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association of Obstetricians and Gynecologists, The Homestead, Hot Springs, Va., Sept. 8-10. Dr. Frank R. Lock, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American College of Hospital Administrators, Convention Hall, Atlantic City, N. J., Sept. 17-19. Mr. Dean Conley, 620 North Michigan Ave., Chicago 11, Executive Director.

American Congress of Physical Medicine and Rehabilitation, Hotel Statler, Detroit, Aug. 28-Sept. 2. Dr. Frances Baker, 30 North Michigan Ave., Chicago 2, Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 10, Director.

American Medical Writers' Association, Jefferson Hotel, St. Louis, Sept. 30-Oct. 1. Dr. Harold Swanberg, P.O. Drawer 110, Quincy, Ill., Secretary.

American Physiological Society Fall Meeting, Tufts College, Medford, Mass., Sept. 6-9. Dr. Allan C. Burton, Univ. of Western Ontario, London, Ont., Canada, Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-23. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Plastic and Reconstructive Surgery, Atlantic City, N. J., Sept. 25-30. Dr. Kenneth L. Pickrell, Duke Hospital Durham, N. C., Secretary.

Association of American Physicians and Surgeons, Chicago, Oct. 7-8. Mr. Harry E. Northam, 185 N. Wabash Ave., Chicago 1, Executive Secretary.

Biological Photographic Association, Wisconsin Hotel, Milwaukee, Aug. 30-Sept. 2. Miss Jane H. Waters, Box 1668, Grand Central P.O., New York 17, Executive Secretary.

Central Association of Obstetricians and Gynecologists, Deshler-Hilton Hotel, Columbus, Ohio, Oct. 5-8. Dr. Edwin J. DeCosta, Suite 602, 116 S. Michigan Ave., Chicago 3, Secretary.

Clinical Orthopaedic Society, Skirvin Hotel, Oklahoma City, Sept. 30-Oct. 1. Dr. Marcus J. Stewart, 869 Madison Ave., Memphis, Tenn., Executive Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10. Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N.W., Washington 6, D. C., Executive Director.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Sept. 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Texas, Chairman.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 3-6. Dr. W. M. Kitchen, 306 E. Twelfth St., Kansas City 6e, Mo., Secretary.

Kentucky State Medical Association, Louisville, Sept. 27-29. Mr. J. P. Sanford, 620 S. Third St., Louisville, Executive Secretary.

Michigan State Medical Society, Pantlind Hotel, Grand Rapids, Sept. 26-30. Dr. L. Fernald Foster, 606 Townsend St., Lansing 5, Secretary.

MIDWEST CONFERENCE ON RHEUMATIC DISEASES, Henry Ford Hospital, Detroit, Oct. 5. Mr. Lewis S. Robinson, 7338 Woodward Ave., Detroit 2, Secretary.

MISSISSIPPI VALLEY MEDICAL SOCIETY, Jefferson Hotel, St. Louis, Sept. 28-30. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

MISSISSIPPI VALLEY TRUDEAU SOCIETY, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

MONTANA MEDICAL ASSOCIATION, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

NEW ENGLAND HEALTH INSTITUTE, Colby College, Waterville, Me., Aug. 30-Sept. 1. Dr. Edward W. Colby, City of Portland Health Dept., Portland, Me., Chairman.

NEW HAMPSHIRE MEDICAL SOCIETY, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

NORTH TEXAS-SOUTHERN OKLAHOMA FALL CLINICAL CONFERENCE, Wichita Falls, Tex., Sept. 17. Dr. E. C. Bebb, Broad St., Wichita Falls, Tex., Chairman.

OREGON STATE MEDICAL SOCIETY, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Carter, 1020 S.W. Taylor St., Portland 5, Secretary.

PACIFIC DERMATOLOGIC ASSOCIATION, Mexico, D. F., Mexico, Aug. 22-24. Dr. Ben A. Newman, 436 N. Roxbury Drive, Beverly Hills, Calif., Secretary.

PENNSYLVANIA, MEDICAL SOCIETY OF THE STATE OF, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

POSTGRADUATE ASSEMBLY IN ENDOCRINOLOGY AND METABOLISM, Indianapolis, Sept. 26-Oct. 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

REGIONAL MEETINGS, AMERICAN COLLEGE OF PHYSICIANS:

- Jamestown, N. D., Sept. 10. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.
- Madison, Wis., Oct. 15. Dr. Howard Wakefield, 122 S. Michigan Ave., Chicago 3, Governor.

SOCIETY OF GENERAL PHYSIOLOGISTS, Marine Biological Laboratory, Woods Hole, Mass., Sept. 9-10. Dr. A. M. Shanes, National Institutes of Health, Bethesda 14, Md.

SOUTHWESTERN SURGICAL CONGRESS, Muehlebach Hotel, Kansas City, Mo., Sept. 5-7. Dr. C. M. O'Leary, 207 Plaza Court Bldg., Oklahoma City, Secretary.

TENNESSEE VALLEY MEDICAL ASSEMBLY, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

U. S. CHAPTER, INTERNATIONAL COLLEGE OF SURGEONS, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

UTAH STATE MEDICAL ASSOCIATION, Union Bldg., Salt Lake City, Sept. 8-10. Mr. H. Bowman, 42 S. Fifth East St., Salt Lake City 2, Executive Secretary.

VERMONT STATE MEDICAL SOCIETY, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. Dr. James P. Hammond, 337 South St., Bennington, Secretary.

WASHINGTON STATE MEDICAL ASSOCIATION, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

WESTERN ASSOCIATION OF RAILWAY SURGEONS, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

FOREIGN AND INTERNATIONAL

AUSTRALASIAN MEDICAL CONGRESS, Sydney, N.S.W., Australia, Aug. 20-27. For information write: Federal Council of the B.M.A. in Australia, 135 Macquaire St., Syndey, N.S.W., Australia.

WORLD CONGRESS OF ANESTHESIOLOGISTS, Scheveningen, Netherlands, Sept. 5-10. For information write: Mr. W. A. Fentener van Vlissingen, Noord-Houdringelaan, 24, Bilthoven, Netherlands.

WORLD CONGRESS ON FERTILITY AND STERILITY, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

WORLD MEDICAL ASSOCIATION, Vienna, Austria, Sept. 20-26. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Part I*, Sept. 6-7. Candidates may file applications at any time, but the National Board must receive them at least six weeks before the date of the examination. New candidates should apply by formal registration; registered candidates should notify the board by letter and forward their fees. Exec. Sec., Dr. John B. Hubbard, 133 South 36th St., Philadelphia 4.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral.* New York City, Oct. 23-27. *Written.* Various locations in United States and Canada, July 20, 1956. Final date for filing application is Jan. 20. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral.* Washington, D. C., Oct. 14-16. Final date for filing application was March 15. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32, N. Y.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* Portland, Ore., Sept. 14-16; Chicago, Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of applications for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination is October 1; for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, Feb. 3, 1956. Final date for filing application is Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

AMERICAN BOARD OF OPHTHALMOLOGY: *Practical Examination.* Chicago, Oct. 3-7. Final date for filing application for 1955 practical examination was July 1, 1954. *Written.* January, 1956. Final date for filing application was July 1. *Practical Examination.* St. Louis, Oct. 20-25. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Final date for filing application for the Part II examination to be given in January 1956 is Aug 15. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* Chicago, Oct. 3-7. Final date for filing application is April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

AMERICAN BOARD OF PATHOLOGY: *Written and Practical.* Chicago, Oct. 6-8. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Chicago, Oct. 7-9; and Washington, D. C., Dec. 2-4. Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

AMERICAN BOARD OF PHYSICAL MEDICINE AND REHABILITATION. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

AMERICAN BOARD OF PLASTIC SURGERY: *Oral and Written.* Philadelphia, Sept. 22-24. Corres. Sec., Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

AMERICAN BOARD OF PREVENTIVE MEDICINE: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

AMERICAN BOARD OF PROCTOLOGY: *Part II.* Philadelphia, Sept. 17. Sec., Dr. Stuart T. Ross, 131 Fulton Ave., Hempstead, N. Y.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: San Francisco, Oct. 17-18; New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Part I.* Centers throughout the United States, in Europe and in the Far East, Oct. 26 and March 28. Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Buffalo, Sept. 26-27; Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

THE BOARD OF THORACIC SURGERY: *Written.* Various Centers, Sept. 9. Final date for filing applications was July 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Tuesday, Aug. 23

CBS-TV, 10:30 p. m. EDT. "The Search" presents a program filmed at Tulane University entitled "New Hope for the Mentally Ill."

Wednesday, Aug. 24

NBC-TV, 10 a. m. EDT. "Home's" report on "Medicine and Health" with Howard Whitman.

MAGAZINES

Parade, Aug. 21, 1955

"A Bandage You Spray On"

Hospitals now use a liquid plastic bandage that is sprayed on from a can.

Coronet, September, 1955

"Chemistry Is Curing Sterile Men," by Selwyn James

"Thanks to a new and effective treatment for male sterility developed by research doctors (Oreton—a synthetic version of testosterone propionate) many of the two million involuntarily childless husbands are offered an excellent chance of becoming parents. . . . Discarded years ago as worthless in the treatment of sterility problems, testosterone today is becoming a major tool because of its strange, delayed reaction when given in controlled dosages to sterility cases that previously have failed to respond to other therapies."

Family Circle, September, 1955

"The Low Days Are Looking Up," by Harold Mehling

A doctor at New York Medical College "evolved a carefully balanced formula that combined the most effective drugs that had been used against each of premenstrual tension's emotional and physical symptoms. For convenience it was put into the form of a coated tablet." After further investigations and tests, during which the doctor found improvement among 9 out of 10 of his patients, he submitted his findings to a research laboratory. Here a tablet was developed that now is available nationally in pharmacies.

Better Living, September, 1955

"Can Allergy Be Prevented," by Dr. Bret Ratner

A New York Medical College professor gives detailed information on allergy. He concludes: "As allergy research moves ahead, the chances are excellent that we will not only learn more about preventing and treating allergic ills but also acquire new insight into how our bodies may be helped to battle more successfully against a number of other ever-present threats, from rheumatism to the common cold."

"A Good Life for Tommy," by Genevieve Catalonotto as told to Ann Eliasberg

A mother tells of problems encountered in raising a Mongolian child.

DEATHS

Jack, Horace Wesley ⊕ Camden, N. J.; born in Collingswood, N. J., Feb. 6, 1894; Hahnemann Medical College and Hospital, Philadelphia, 1917; specialist certified by the American Board of Surgery; served in France during World War I; fellow of the American College of Surgeons and the International College of Surgeons; member of the Philadelphia Academy of Surgery, College of Physicians of Philadelphia, and the Society of Surgeons of New Jersey; past-president of the Camden County Medical Society and the West Jersey Medical Society; chairman of the cancer control committee of the Medical Society of New Jersey; vice-chairman of the medical advisory committee of New Jersey Division of the American Cancer Society; member and formerly chairman of the executive committee of the Camden County Cancer Society; on the staff of the West Jersey Hospital; consulting surgeon, Camden County General Hospital in Lakeland; died in the Graduate Hospital, Philadelphia, June 20, aged 61, of hemorrhage from esophageal varices and cirrhosis of the liver.

Navy; fellow of the American College of Surgeons; member of the Industrial Medical Association; died April 14, aged 53, of hemorrhage due to laceration of the scalp.

Skarperud, Arthur M. ⊕ Aberdeen, Wash.; University of Illinois College of Medicine, Chicago, 1924; served during World War I; past-president of the Grays Harbor County Medical Society; on the staff of St. Joseph Hospital; died June 20, aged 60, of injuries received in a tractor accident.

Slater, Harvey Maurice, Menlo Park, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1915; died June 29, aged 69, of coronary occlusion.

Sparks, Clara Ellita Pratt, Gustine, Calif.; Cooper Medical College, San Francisco, 1907; died June 25, aged 74, of heart disease.

Story, Charles Butts ⊕ Bayside, N. Y.; University of the City of New York Medical Department, 1890; an associate member of the American Medical Association; past-president of the Queens Medical Society; formerly health officer of borough of Queens; served as chief surgeon and chief of staff of the Flushing (N. Y.) Hospital; a director of the First National Bank of Bayside; died in the Eastern Long Island Hospital in Greenpoint July 2, aged 91, of cerebral hemorrhage.

Stubenbord, Jess ⊕ Buffalo; University of Buffalo School of Medicine, 1937; specialist certified by the American Board of Surgery; served during World War II; fellow of the American College of Surgeons; on the staff of the Deaconess Hospital, where he died May 19, aged 49, of coronary thrombosis.

Twist, Earl Bancroft, Chatham, N. J.; New York University Medical College, New York City, 1898; member of the Medical Society of the State of New York; for many years examining physician for the Prudential Insurance Company; died in the Morristown (N. J.) Memorial Hospital June 1, aged 85, of arteriosclerosis and heart disease.

Wees, Marshall Paul ⊕ La Jolla, Calif.; University of Michigan Medical School, Ann Arbor, 1943; interned at St. Mary's Hospital in Saginaw, Mich.; served during World War II; died June 15, aged 49.

Westly, Gabriel S. ⊕ Manly, Iowa; State University of Iowa College of Medicine, Iowa City, 1916; served during World War II; on the staff of St. Joseph's Mercy Hospital in Mason City; died June 3, aged 68, of carcinoma of the rectum.

FOREIGN LETTERS

AUSTRIA

Ganglion Blocking Agents.—At the meeting of the Austrian Society for Gynecology and Obstetrics in May in Velden am Wörthersee, Dr. R. Riegler of Graz said that there are three ways in which the neurosympathetic ganglions can be interrupted by blocking agents: (1) suppression of the secretion of acetylcholine, which is the important substance in transmission; (2) suppression of the liberated acetylcholine; and (3) permanent depolarization of the cellular membrane in the peripheral neuron. Knowledge as to whether a ganglion blocking agent acts by suppression of acetylcholine or paralyzes the muscles by depolarization is important in connection with the weakening of intensification of this effect by substances inhibiting cholinesterase. Paralysis can be abolished by agents that block the cholinesterase only in patients in whom the blockage is caused by suppression, whereas in cases of depolarization the opposite effect results.

Hemorrhagic Diathesis.—At the same meeting Dr. E. Deutsch of Vienna stated that the differentiation between thrombocytic and vascular hemorrhagic diathesis is possible only on the basis of the coagulation mechanism that can be determined in the laboratory. In acute hemorrhages transfusion with whole blood is required. Plasma expanders may be used only if an exact diagnosis has been established. In the toxemias of pregnancy afibrinogenemia and the clotting caused thereby can be caused by a reactive fibrinolysis. Shock may lead to the liberation of heparin-like substances. Therapy consists of infusions of 8 to 10 gm. of purified fibrinogen and the injection of 5 to 10 cc. of 1% solution of protamine sulfate.

Eclampsia.—At the same meeting Dr. H. Wimhöfer of Heidelberg said that the frequency of eclampsia in the region of Heidelberg was 0.2% between 1940 and 1953 and 78.2% of the patients were primiparas. During World War II eclampsia decreased, but this decrease was evident before the food supply became greatly curtailed. Between 1944 and 1948 eclampsia increased again, although foods were still in limited supply. This seems to indicate that in addition to a nutritional factor a psychic factor plays a part in the production of eclampsia. The speaker further analyzed and classified late gestoses into essential and secondary gestoses caused by and superimposed on other disorders. In only 35 of 80 women with late gestoses was the subsequent pregnancy a normal one; 28 had preeclampsia and 14, eclampsia. Of the women with eclampsia, 6% had a normal blood pressure. This does not contradict the theory of arteriolar spasm. The case fatality rate increased with rising oliguria, and an increase in the attack rate was likewise accompanied by an increase in mortality, but the increase in time between the first attack and the delivery did not influence the case fatality rate. The speaker stressed the value of a diet that is rich in vitamins and in high-grade proteins but has a low sodium chloride content. The presence of hypoproteinemia indicates a serious condition, and when this occurs it is advisable to give milk proteins, preserved plasma, amino acid mixtures, and methionine. Hypertonic dextrose solutions and Periston (a plasma expander) may be given in quantities of from 200 to 400 cc., particularly to patients in whom the eclampsia has caused pulmonary edema. The maternal mortality rate was 16.9% in 189 eclamptic women in whom cesarean section was performed and 6.3% in 411 women who were hypotensive and received conservative treatment. The fetal mortality rate was 7% with active treatment and 10% with conservative treatment.

Dr. E. Ostergaard of Copenhagen said that in Denmark most babies are delivered in the home. In Copenhagen, however, about 80% of all deliveries take place in hospitals. In 1945 a law was passed entitling all pregnant women to three examinations by a physician and to six examinations by a midwife at the expense of the state. A Wassermann reaction and examinations to ascertain the Rh factors are also free. Eclampsia has been treated for many years according to the conservative method of Stroganoff. In 1936 the maternal mortality rate was 0.53% and in 1953 only 0.1%. The frequency of eclampsia was 2.3% between 1935 and 1940 and 1.2% between 1948 and 1953, and the speaker believes that this improvement is the result of the welfare law. The physician is required to hospitalize any pregnant woman whose systolic pressure rises over 150 mm.

Leinzinger and Ribitsch of Graz said that, of 56,505 women delivered between 1925 and 1954, 335 or 5.9% had eclampsia. Of these, 74.8% were primiparas. Of the eclamptic attacks, 2% were recurrences, and 8% of the women with eclampsia delivered twins. The war had no noticeable influence on the incidence of eclampsia. It proved impossible to establish a connection between eclampsia and such factors as meteorologic conditions, sun spots, or terrestrial magnetism. The maternal mortality rate was 13.7%, and the infant mortality rate was 27.9%. Delivery was surgical in 47.2%.

Prolonged Pregnancy.—At the same meeting Dr. S. Kolonja of Klagenfurt said that prolongation of pregnancy was observed in 775 of his series of 8,000 deliveries. The pregnancy that continues beyond the computed term involves no particular danger for the infant. Waiting for spontaneous delivery is advisable. When no measures were taken to induce delivery, no fetal death that could be ascribed to the prolongation of pregnancy occurred, but fetal mortality and the need for operative intervention was multiplied several times when delivery was induced by means of drugs. It is necessary to differentiate between true prolongation of pregnancy and a belated delivery due to endogenous factors.

Amenorrhea.—At the same meeting Dr. E. Leinzinger of Graz said treatment was justified for amenorrhea of short duration, citing psychic and psychosomatic factors and pointing out that there is a danger that the brief amenorrhea may become prolonged. In 157 patients with amenorrhea of short duration a 1:10 mixture of estrogen and progesterone was used; 53 of the women treated were pregnant and in 4 of these abortion resulted, which, however, could not be ascribed to the treatment. Psychic factors may be responsible for amenorrhea. Treatment is especially necessary when amenorrhea of short duration shows a tendency to recur. The treatment described may be effective in as high as 96.4% of the patients.

Cortisone in the Treatment of Sterility.—At the same meeting Dr. A. Netter of Paris stated that increased 17-ketosteroid values were found in the urine of women with anovulatory cycles caused by corpus luteum insufficiency. Three of these women, in whom the anatomic conditions appeared normal, were given cortisone. One woman had a bilateral hydrosalpinx, for which she had received conservative treatment between 1951 and 1954. She conceived following treatment with cortisone and was able to carry the pregnancy to term and give birth to a normal infant. In two other women spontaneous ovulation was induced by treatment with cortisone. The mode of action of this treatment has not been completely explained.

Adnexal Tuberculosis.—At the same meeting Dr. H. Knaus of Vienna pointed out that adnexitis in children between 10 and 15 years of age is usually tuberculous. Of 75 patients in whom tuberculous salpingitis was histologically verified, 56 had peritoneal tuberculosis. This indicates the close connection between peritoneal and genital tuberculosis. A peritoneal tuberculosis is possible only if the tubal ostium is patent. The primary process is always in the tube. In 35 of 70 patients curettage was performed one year after the operation, and in three of these the endometrial material still showed tuberculosis. These patients were given three weekly instillations of 150 mg. of isoniazid for a period extending over two menstrual cycles. In all three of

The items in these letters are contributed by regular correspondents in the various foreign countries.

these patients the endometrial tuberculosis was cured. A tuberculous fistula likewise was cured after scraping and instillations of isoniazid. For genital tuberculosis the author recommends removal of the uterine tubes.

Urinary Incontinence.—At the same meeting Froewis and Palmrich of Vienna stated that for the diagnosis of closure incontinence it is usually sufficient to fill the bladder and make an examination while the patient is standing, while coughing, and while pressing. In this way pseudoincontinence can be excluded. This condition can be recognized also in the cystogram that indicates the form of micturition. The cystogram also permits differentiation between the vertical and rotary descent of the bladder. In patients with vertical descent, a lifting of the region of the sphincter will counteract incontinence. In rotary descent, however, or when descent is absent, only an operation that will affect compression of the urethra, or conservative measures that increase the tonus of the closure apparatus, such as hormonal therapy and gymnastics, will be effective. Dondren, which was used in 100 patients, produced cure in 50%, and in 33% it produced marked improvement.

ENGLAND

Patients, Politics, or Both?—Dr. R. Hale-White, president of the metropolitan counties branch of the British Medical Association expressed the view (*British Medical Journal*, supp., p. 225, May 14, 1955) that it was a physician's duty to take a personal part in medical politics. If he is to serve the best interests of his patients, it is as important that a physician devote a part of his time to medical politics as it is that he keep abreast of advances in scientific medicine. As an example of the muddled state of the National Health Service, Dr. Hale-White referred to the fact that, although it is claimed that many physicians are overworked, it is difficult for a young man to enter the service and even more difficult for an aging physician to ease off. It is exceedingly hard for a general practitioner to do what he would wish for his patients and in most cases practically impossible for him to follow them through an illness in a hospital. Dr. Hale-White believes that the working of the National Health Service would have been much worse had it not been for the British Medical Association's council meetings and representative meetings in the last 10 years; regulations and directions relating to what a physician might or might not do would have descended on the profession like confetti. The general practitioner might easily have been told by a government department by what signs and symptoms he could reach a certain diagnosis and what action to take when the diagnosis was reached.

The common supposition that British medicine and the National Health Service are synonymous is false. So far, the country has been spared a state monopoly in medicine, which was the undoubted aim of those who introduced the National Health Service. The fact that private practice still exists is a blessing not because private practitioners are necessarily better than their colleagues in the service but because, as long as there are two systems in healthy competition, complete disaster cannot overwhelm British medicine, and the public still has free choice in medical care. The most helpful contribution toward keeping private practice alive has been made by two or three insurance companies, one of which in the last four years has increased its membership from 60,000 to 200,000. There must now be more than 500,000 people entitled to a large proportion of the cost of their hospital and specialist treatment through these companies. In Dr. Hale-White's opinion the standard of medical practice in the country is going down and will continue to go down unless far-reaching changes are made. Those who are worried about the future of medicine in this country should not hesitate to say so. Censure of the National Health Service would be much greater were it not for indolence and cowardice. Tinkering with the service is not sufficient. If a large body in the profession really believes that the public is not getting the best service the country can afford, the first thing to do is to say so, and the next is to devise a better system in which a full-time salaried service as an alternative should not even be considered.

Inadequacies in Hospital Administration.—In the report of the Hospital Discussion Group, published in the June issue of the *Hospital*, the view is expressed that, should the quality of administration be low and an atmosphere of ministry rules and regulations, auditors' queries, and general subservience to the vast impersonal machine of central control prevail, a slow decline in the quality of hospital service will be inevitable. The criticism is made that the caliber of senior hospital administrators is sometimes unequal to the responsibilities of their position. Young men of the potential caliber to bear these heavy responsibilities are not easily found within the existing service, and, if recruits are to be attracted from without, they must be offered not only an ultimate salary commensurate with their responsibilities but also a course of training that will equip them for their duties in the shortest possible time.

Some hospital authorities have established trainee posts with the object of attracting into the administrative service university graduates and others considered suitable for senior posts, but there is a certain amount of opposition from within the service itself to such selective entry. Although promotion within the service should be encouraged, it should not be assumed that there is any intrinsic merit in this laborious ascent nor that the successful negotiation of the lower rungs gives one a head for heights. Training schemes that expect to attract new entrants into the lowest clerical grade are unrealistic. A training scheme has been outlined, extending over three years, and it is recommended that the age of entry should be at least 23. After an introductory three months at a hospital staff college, the trainees would spend 18 months in designated trainee posts attached to hospital management committees, boards of governors, or regional hospital boards. The next three months would be spent under the direction of the staff college for a course of instruction in all aspects of administration. During the final year the trainees would be attached to the central administration of a hospital management committee or board of governors as personal assistants to the chief administrative officers.

Number of Hospital Beds.—Do we need more beds to deal with our waiting lists? Can we afford to maintain these additional beds? These are two of the problems dealt with in the current issue of the *West London Medical Journal* (60:95, 1955). There is too rigid a system of allocation of beds to specialists. Consultants should be prepared to transfer beds to other colleagues as circumstances demand. The seasonal variation in the demand for accommodation should be borne in mind. Further, there should be sufficient flexibility to allow wards designated for men to be used for women, and vice versa. Local health authority services are not being used sufficiently. An efficiently used health visitor service could reduce the demand for hospital beds by caring for patients in their homes under the direction of a physician. The provision of large and better organized outpatient departments, with adequate diagnostic facilities geared to local health and general practitioner services, would also reduce the demand on hospital bed space. In plans for hospital extension, provision should be made for hostels, where patients could stay while undergoing radiotherapy and physical therapy. The introduction of "day hospitals" for the care of patients with senile dementia and the victims of mild mental disorders is also recommended. Some of the small uneconomical cottage hospitals might better serve the community as health centers.

Megaloblastic Anemia Due to Phenytoin.—Two further cases of megaloblastic anemia apparently due to phenytoin have been reported by N. Berlyne and his co-workers (*Brit. M. J.* 1:1247, 1955). Both were in epileptic subjects, aged 28 and 26, respectively, and both subjects had been taking phenobarbital and phenytoin. The first had been taking these two drugs for at least 18 months, and, at the time when the anemia was detected, the dosage was 100 mg. of phenytoin and 50 mg. of phenobarbital three times a day. The subject's erythrocyte count fell to 1,800,00 per cubic millimeter, with 25% hemoglobin. The second subject had been taking phenobarbital and phenytoin for four years, and the current dosage was 100 mg. of phenytoin and 32 mg. of phenobarbital three times a day. His erythrocyte count was 1,600,000 per cubic millimeter, with 28% hemoglobin. Both had free hydrochloric acid in the gastric juice. In both, the anemia failed to respond to cyanocobalamin but responded promptly and completely to folic acid, even though the administration of both phenytoin and phenobarbital was maintained all the time. In neither patient was there any evidence of nutritional deficiency, steatorrhea, or liver disease, and neither had had any gastrointestinal operations. Phenytoin is believed to act as a folic acid antagonist, but this complication of phenytoin therapy is relatively rare.

Hypnotism in Dermatology.—Dr. Hugh Gordon investigated the effect of hypnotism in 144 dermatological patients (*Brit. M. J.* 1:1214 [May 14] 1955). The suggestion was given patients during hypnosis that the skin condition would resolve and return to normal and that irritation, if present, would disappear. In most of the conditions treated, pruritus was a troublesome feature, and the antipruritic effect of hypnosis was often marked. Later in the investigation, psychotherapy was added to hypnosis. Dr. Gordon found that the psychic factor was important in degrees varying from 100% down to 50% in a wide range of common skin disorders. One boy of 12, who had had eczema and asthma from the age of 2, was completely cured of both in about six sessions. He was still clear two and one-half years later. The series included many patients with atopic eczema, and some of them had been extremely resistant to treatment. In another patient with dermatitis herpetiformis of 10 years' duration, the condition had been controlled by arsenic, but this had to be withdrawn because of severe and obscure retinal lesions. These improved when the arsenic therapy was stopped, but the dermatitis relapsed. Both skin and eye lesions cleared up rapidly under hypnosis and psychotherapy and had remained so at the time of a two year follow-up.

Myxomatosis and Man.—There is a certain amount of public anxiety concerning the possibility of transmitting myxomatosis to man. In a recent issue of the *Practitioner* (174:709, 1955), Dr. E. J. Moynahan, who was called in to see the first alleged human case of myxomatosis in this country last year, states categorically that man cannot be infected. There are several diseases that bear a superficial resemblance to myxomatosis and that the patient or his relatives may confuse with the animal disease. These include bullous erythema multiforme, ectodermosis erosiva pluriorificialis (Stevens-Johnson syndrome), atypical cases of chickenpox and smallpox, bullous dermatitis herpetiformis, pemphigus vulgaris, angioneurotic edema, and certain drug rashes. Persons handling sick rabbits may develop localized or systemic infections, through cuts or abrasions, due to the common pyogenic organisms. These infections may give rise to anxiety in the patient and his relatives unless they are recognized for what they really are.

Mitral Valvotomy at Full Term.—A 35-year-old woman with pure mitral stenosis had a valvotomy performed 10 hours before the birth of her ninth child (*Brit. M. J.* 1:1191, 1955). She was admitted to the hospital in the early stages of labor. During her previous pregnancies she could recall no notable symptoms, nor did she know of any abnormality of the heart. She gave a history of persistent nonproductive cough of six weeks' duration and was found to have dyspnea, orthopnea, cyanosis, and a hemoglobin of 55%. Clinically and radiologically she had the classical findings of mitral stenosis, and, in view of the rapid deterioration in her condition after admission, it was decided to perform an emergency valvotomy. This revealed a tight stenosis, but both commissures separated without difficulty. The patient was returned to the ward in a satisfactory condition, and 10 hours later a live infant, weighing 8 lb. (3,628.7 gm.) was born without difficulty or distress to the mother.

Experimental Health Center.—The second health center to be built in Scotland has been opened at Stranraer. The aim of the center, which is experimental, is to bring the different health services closer together and to enable them to cooperate to the advantage of the patient in the common aim of preventing as well as curing ill-health. The building, which covers 7,000 square feet, is built in an L-shape and incorporates an extension to the adjoining Garrick Hospital. One wing provides five consulting suites for the five family physicians who practice in Stranraer and who between them have a total of 13,200 National Health Service patients. In the other wing the local authority has three rooms and a dental room for its own use and will share another four with the board responsible for running the Garrick Hospital. In addition, the hospital has for its own use a changing room, a plaster room, and a suite for the x-ray unit.

How State and Voluntary Services Saved a Family.—In spite of the welfare state, people are still dependent on ancillary agencies for the successful solution of their troubles. A father, mother, and four young children, all apparently healthy, emigrated to Australia. On arrival it was found that the father and one of the children had pulmonary tuberculosis, and the family had no option but to return. They arrived in Bournemouth having exhausted their savings, with nowhere to live, no income, no resources, and no prospects. The father was sent for long-term treatment, and within a fortnight the family, now on National Assistance, was brought before the special hardship committee and a house was allocated to them. The voluntary tuberculosis care committee provided all that was necessary to set up home. Of the money spent by the care committee, some was recovered from service funds (the couple having served during the war) and the National Assistance Board. The women's voluntary services also contributed furniture, and the Soldiers, Sailors, and Air Force Association helped with clothing. Volunteers also helped in establishing the home. Two children had since been admitted to a sanatorium, and, throughout, a constant checkup was made to ensure that the most urgent needs were met. Response to help from all sides was so remarkable that the family was overwhelmed with gratitude. Most important of all, the father was able to go through his hospitalization with his mind freed from worry concerning the security of his home and family.

Critics of the National Health Service.—The physicians of any country in which initiation of a health service in the pattern of the British National Health Service is being considered, would do well to read the two opening articles in the *British Medical Journal* of April 30. These articles are by a middle-aged consultant and a young general practitioner respectively. An editorial in the same issue states that the worst thing that could happen to medicine in England would be an apathetic acquiescence of the working of the National Health Service. The profession is entangled in a mass of forms, committee reports, and an endless stream of administrative regulations. Neither the consultant nor the general practitioner complain of poor remuneration or overwork. The established young general practitioner in partnership practice today has a much easier time than his predecessors. He has a secure, pensionable job, but the fear of litigation has stifled the initiative that has done so much to improve medical and surgical practice. Apathy and a deterioration of standards are beginning to be evident, and there is a widening gap between the hospital staff and the general practitioner.

Upgrading Mental Nursing.—Hospital authorities in England and Wales have been asked by the Minister of Health to promote wherever possible the interchange of student nurses between general and mental hospitals as a means of improving the quality of the mental nurses's training, introducing a valuable element into the training of general nurses, and breaking down the isolation from which many mental hospitals still suffer. The General Nursing Council has agreed that for student mental nurses a six months' assignment to a general hospital would be satisfactory. The council has also agreed to consider proposals for the assignment of student general nurses to mental hospitals for part of their training.

Ophthalmic Hospital of St. John.—Sir Stewart Duke-Elder has been instrumental in finding a site for the rebuilding of the Ophthalmic Hospital of St. John in Jerusalem. A new site has been purchased outside the old city, and it is hoped that the building will be finished by the end of 1956. The present hospital has 45 beds, but the new one will have 70 beds and, in addition, a special wing to house the research institute. The latter will have a separate staff but will be under the control of the Order of St. John. The staff of the institute, when complete, will consist of a medical director, three British scientists, three Arab scientists, and a number of technicians. Research on trachoma will be an important part of the work of the institute. The initial cost of the hospital and institute is expected to be about $700,000.

Dellwood Fire.—The *British Medical Journal* of April 16 publishes the account of the effects of the Dellwood Fire by Drs. M. E. Cox and her co-workers. In the early morning of Easter Sunday (April 18, 1954) a fire in the nursery of the Dellwood Maternity Home resulted in the death of 13 newborn babies. The fire was caused by the flue of a hot-water boiler, which in September, 1953, had been moved, so that it ran beneath the floor of the nursery. It was subsequently established that the installation of the flue complied with the local building regulations, but the regional board in their inquiry agreed that the regulations needed revision. It seems likely that the fire began slowly, with much smoldering of wood over a large area of floor. This filled the room with thick smoke, until, finally, part of the floor ignited and the flames spread to one of the cots. It is thought that the room may have been filled with smoke for between 20 and 30 minutes. There were 15 babies in the nursery, the doors of which were closed. Two nurses were on duty, and the nursery was visited at intervals during the night, the last visit before the fire being at about 3:15 a. m. The fire was discovered by one of the nurses at 4 a. m., and she immediately began to remove the babies from the room while help was being called. While removing the first babies she received severe burns of face and arms and was in great distress from the inhalation of smoke. She continued to bring them out one by one and collapsed when the last one had been carried out. She was admitted to the hospital and was later decorated by the Queen.

Signs and Symptoms.—One of the authors first saw the babies at 4:30 a. m. The baby whose cot had caught fire was dead due to extensive burns. Three others were transferred to the Battle Hospital at once and placed in oxygen boxes. All three were limp and pale and in great respiratory distress. There was much clear viscid discharge from the nose and eyes and complete nasal obstruction. The remaining 11 babies were in good general condition, but all were coughing and had some discharge from the nose and eyes. Their color was generally good apart from slight occasional cyanosis produced by coughing attacks and interference with breathing by nasal obstruction. During the day there was some deterioration. Respiratory rates rose, and the coughing increased. Scattered rales became audible in every child in the afternoon and evening. All were kept in oxygen boxes.

Treatment.—Early on Monday morning all the surviving babies were transferred in oxygen boxes to the Royal Berkshire Hospital. An alarming increase in respiratory obstruction developed in all the infants, and on Monday evening it seemed unlikely that any of them would survive. Two of the babies began to improve after the third day and finally made a good recovery. There is no reason to suppose that these two suffered less exposure to the smoke than any of the others. In addition to oxygen therapy, mucous secretions were aspirated at intervals as needed, and 5% sulfacetamide was applied to the nose and eyes. Penicillin was given, starting on the morning of the first day. Humidification was maintained by electric steam kettles. At midday on Monday treatment with streptomycin and cortisone was started. Feedings, at first with glucose-saline solution and later with a milk mixture, were given by esophageal tube during the first 48 hours. Aspiration of the trachea was attempted in three babies without apparent benefit, and hardly any mucus was obtained by this method. In those babies who survived the first 48 hours, percussion drainage was attempted, in addition to postural drainage and frequent changing of position. This seemed to produce some good results: mucus was coughed up and aeration seemed to have improved. In one of those who recovered, a large bronchial cast was aspirated from the nose on the sixth day, after one of these periods of percussion drainage.

Comment.—The most important question that arises is whether anything further could have been done to help these babies. Atropine might have been given in sufficient doses to diminish secretion. It might, however, also have made secretions more viscid and less likely to separate. Humidification by mist, perhaps with the addition of a detergent, might have been used, but this could have led to a fatal increase in the already great amount of fluid in the lungs. Cortisone might have been given earlier and in larger doses, but, in addition to diminishing exudative responses, cortisone promotes fluid retention and possibly diminishes resistance to infection. More vigorous and intensive aspiration of the lower respiratory tract might have been attempted, including aspiration through tracheotomies, but such procedures in newborn infants have their own risks and probably a high mortality rate. They might, however, have been effective in the babies who survived to the third day, when some of the casts were beginning to separate. The custom of putting all the babies into a nursery for the night so that the mothers can sleep undisturbed is widespread and is the rule in small maternity homes. Apart from the possibility of a disaster such as this, the system is bad. The proper place for the normal newborn baby is in a cot close to the mother's bed.

FRANCE

Cardiopericardiopexy.—In the *Archives of Cardiac and Vascular Diseases* of February, 1955, A. N. Gorelik presents the results of 150 cases treated by cardiopericardiopexy. This operation transforms an ischemic into a hyperemic myocardium through the introduction of talcum powder into the pericardial sac, thus causing an inflammation of the pericardium, myocardium, and adjoining tissues. As a result a granulomatous pericarditis is created leading to the development of anastomotic intercoronary vessels. Gorelik modified the former procedure of Thompson by resecting the left costal cartilage and its perichondrium in order to allow the development of new vessels between the pectoralis major and the pericardium. The author has also extended the indication of this method, which was originally used to relieve angina pectoris, to include certain complications of acute rheumatic fever. He reports a series of 50 patients with far-advanced rheumatic cardiopathy and 100 with angina pectoris. In the first category the operative mortality was 12%, but in those who survived the improvement has been remarkable. In the group with angina pectoris the operative mortality was 10%, but in those who survived the results were excellent, and they have been able to resume their normal physical activity without pain or dyspnea.

Chlorpromazine in Gastric Crisis.—At a meeting of the Medical Society of Paris Hospitals in March, R. Moreau and his co-workers reported that in a patient with gastric crisis of tabes, which was not relieved by atropine nor any other drug, a slow perfusion with 50 mg. of chlorpromazine in 500 cc. of isotonic dextrose solution gave prompt and lasting relief. In another patient whose gastric crisis was due to plumbism, an intravenous perfusion with chlorpromazine alone gave complete relief within two hours. The mechanism of this action remains obscure.

Cells Infected with Poliomyelitis.—At the same meeting, Professor Borski and his co-workers of the Pasteur Institute demonstrated by means of microcinematography the appearance of a homogenous eosinophilic mass in the center of fibroblasts taken from a human tonsil 15 to 20 minutes after poliomyelitic viral infection and grown in a culture medium. This mass throws the nucleus and cytoplasm toward the periphery. In some cells contractions were observed when the central mass was half developed. These contractions led to deformity of the nucleus by the rigid inclusion body. At first this deformity was reversible. The nucleus regained its normal form after each early contraction but progressively became flattened and thrown aside during the successive contractions. At the moment of the cellular death, it was completely eccentric and flat.

Poliomyelitis.—In May, 1955, at the meeting of the Medical Society of Paris, Vigot and Poilpre of Caen reported on the use of cortisone in patients with paralytic poliomyelitis. Of 13 patients given 50 to 250 mg. of cortisone per day intramuscularly, only one died, and in 7 the paralysis did not progress after 24 hours of this treatment. Five other patients with severe respiratory paralysis all survived.

NORWAY

When to Operate for Gastric Ulcer.—In *Nordisk Medicin* for May 25 Dr. O. Römcke presented statistics far from flattering to the medical treatment his patients had received; only 22% of those with gastric ulcer, 12% of those with pyloric ulcer, and 11% of those with duodenal ulcer were symptom-free eight years after the completion of medical treatment. Hence, his present policy is to recommend operative treatment if the patient relapses after a course of medical treatment in hospital and cannot remain symptom-free on light dietetic restrictions. His advocacy of operation for gastric ulcer, as distinct from duodenal ulcer, is influenced by the greater likelihood of malignant disease in those with gastric ulcer. The swing of the pendulum in favor of surgical treatment is indicated by figures covering the period 1935 to 1949. At the beginning of this period only 19% of the 237 ulcers were operated on, whereas at the end of this period 35% of the 187 ulcers were operated on. Römcke hesitates to recommend an operation for patients over 60, but with the operative mortality falling steadily he has shifted his age limit upwards. Patients in whom neurotic tendencies play an important part are disappointing subjects for operative treatment, and Römcke is also diffident about recommending such treatment for very young patients. In the same issue Dr. C. Bruusgaard said that he advises his patients to eat, drink, and be merry, because ulcers heal when you are merry, and no new ulcer develops if you are always merry.

Epidemic Hepatitis.—Dr. R. A. Jensen, in *Tidsskrift for den norske lægeforening* for June 15, reports two outbreaks of epidemic hepatitis. A woman, aged 29, was admitted to the hospital in February, 1953. Four days after admission she became jaundiced, and because a tentative diagnosis of cholelithiasis was made no steps were taken to isolate her. It was only after she had been jaundiced for 22 days that infectious hepatitis was diagnosed and she was transferred to another ward. After this transfer and during the following eight weeks, infectious hepatitis developed in 11 members of the nursing staff. All 11 nurses had been in contact with the patient, and it is probable that in 9 of these the infection had passed from one nurse to another. This hospital outbreak led Jensen to study the community of about 1,200 persons to which the original patient belonged. In this nsely populated community centering around a school on the outskirts of Oslo, it was found that there had been an outbreak consisting of 24 cases of infectious hepatitis. Epidemiological evidence suggested that the infection had been transmitted by personal contacts. Although this was the most plausible interpretation, the water supply of the community was examined and was found to be heavily polluted, and measures were taken to assure the community a purer drinking water.

TURKEY

Chronic Myelocytic Leukemia.—In *Saglik Dergisi* (vol. 29, no. 1) Erkmen and Yazan reported on Dichloren (a nitrogen mustard proprietary preparation) therapy in two patients with chronic myelocytic leukemia. A woman, aged 45, had a hard and painful abdominal swelling on the left side and was losing weight. On admission she was weak and anemic; her enlarged, hard, smooth, painless spleen had descended 6 cm. below the umbilicus; and her hard, smooth, painless liver was palpable 5 cm. below the costal margin. Her erythrocyte count was 3,400,000 per cubic millimeter; her hemoglobin level 40%; and her leukocyte count 184,500 per cubic millimeter, with 43% metamyelocytes and transitional cells, 26% neutrophils, 12% myelocytes, 10% eosinophils, 7% lymphocytes, 1% premyelocytes, and 1% monocytes. She was given an intravenous injection of 0.1 mg. per kilogram of body weight of Dichloren every other day for eight doses. Forty-eight hours after the first injection a rapid decrease in leukocytes was observed. Within 10 days the count dropped to 55,000 per cubic millimeter and after 21 days, to 9,000 per cubic millimeter. Recession of the spleen was observed on the 4th day, and after 25 days it was no longer palpable. After 20 days the differential leukocyte count was 21% metamyelocytes and transitional cells, 48% neutrophils, 19% lymphocytes, 8% myelocytes, and 4% eosinophils. The patient's general condition was markedly improved, and she had gained 3 kg. (6.6 lb.) in 35 days. On discharge 10 days later, her erythrocyte count had risen to 4 million per cubic millimeter and her hemoglobin level to 60%. A relapse occurred eight months after her discharge from the hospital, and she was given a maintenance dose of 0.1 to 0.3 mg. of Dichloren.

The second patient was a woman, aged 48. On admission she was weak and anemic. Her spleen had descended to the pubis, and her liver was palpable 6 cm. below the costal margin. Both organs were hard, smooth, and painless. Her erythrocyte count was 2,000,000 per cubic millimeter; her hemoglobin level 35%; and her leukocyte count 164,000 per cubic millimeter, with 56% metamyelocytes and transitional cells, 20% myelocytes, 16% neutrophils, 4% premyelocytes, 2% eosinophils, and 2% lymphocytes. Sternal puncture revealed 10% neutrophils, 10% transitional neutrophils, 1% transitional eosinophils, 43% metamyelocytic neutrophils, 4% metamyelocytic eosinophils, 19% myelocytes, 9% premyelocytes, and 4% myeloblasts. The patient received an intravenous injection of 5 mg. of Dichloren every other day for eight doses. Seventy-two hours after the first injection, a marked decrease in leukocytes was observed, and on the 17th day the leukocyte count was 30,000 per cubic millimeter, the erythrocyte count was 3,000,000 per cubic millimeter, and the hemoglobin was 50%. Recession and softening of the spleen was observed after the second injection, and after 17 days it had receded to the umbilicus, the liver had receded 2 cm., and its edges had somewhat softened. The patient's general condition was markedly improved, and she had gained weight. Further improvement was expected, but the patient left the hospital against advice on the 20th day.

Corneal Epithelization of the Anterior Chamber.—In *Eye Klinik* (vol. 9, no. 2) Gördüren and Tosunoglu reported the development of corneal epithelium of the anterior chamber of the eye after a cataract operation. It was the only case observed among the 1,112 patients who had an operation for cataract during a five-year period. The patient was a man, aged 52, who had had a preliminary iridectomy of the right eye and six months later an uncompleted extraction of a cataract. Three years later he had a complete iridectomy for capsular cataract of the left eye. On the seventh postoperative day iridocyclitis was observed. On the 16th day the patient was discharged, and his therapy was continued in the outpatient department. On the 27th day lacrimation and conjunctival congestion was observed. Behind the cornea and below the cicatrix, a fine membrane with notched edges was observed and diagnosed as corneal epithelization of the anterior chamber. The patient was readmitted. In spite of atropine, hot dressings, diathermy, and general therapy for six weeks, the condition progressed. Sensitivity of the cornea decreased, there was deep vascularization, the papilla lacrimalis was raised, and a small fistula was observed at the cicatrix. Gradually covering the corneal center, two transparent nodules on the notched edges of the membrane developed and, with the closing of the fistula and due to intraocular pressure, a secondary glaucoma developed on the 54th postoperative day. On the following day the patient was given x-ray therapy. He received five series of 1,290 r for 10 consecutive days with intervals of one week. On the 12th day the epithelium began to separate and recede upward, and the patient's severe headache subsided.

Apricot Seed Tumor.—Dr. Halil Çiray, gynecologist at Ankara General Hospital, reported a case of intestinal torsion resulting in a tumor in a multipara, aged 30. Menstruation had not occurred for several months. One month prior to admission she had a sudden, severe, abdominal pain associated with vomiting. On admission she had a temperature of 102.2 F and a pulse rate of 120 beats per minute. Her abdomen was distended and tender. Under the naval a hard, smooth, semimobile tumor was palpable. Due to abdominal tenderness, the uterus and ovaries could not be distinguished. A tentative diagnosis of torsion in an ovarian tumor was made. Laparotomy was performed, and a tumor located in the small intestine was found to contain numerous apricot seeds. After excision of the mass, the patient recovered.

CORRESPONDENCE

DESIGNATION OF "TRANQUILIZING AGENTS" IN NEUROPHARMACOLOGY

To the Editor:—An already overburdened glossary provokes misgivings in anyone who proposes to coin a new term. There are occasions, however, when new experience calls for a word to encompass it. Recent clinical use of chlorpromazine and the Rauwolfia fractions has demonstrated that these new compounds are capable of producing amelioration of a wide spectrum of symptoms in psychiatric disorders on occasion and thus "normalizing" such patients. Recently another drug having limited therapeutic qualities of this general type has been reported by me (*Science* **121**:208 [Feb. 11] 1955, and *Neurology* **5**:319 [May] 1955) and is undergoing further study. Alpha (4-piperidyl) benzhydrol hydrochloride, or Frenquel, is effective in the prevention and treatment of model psychoses produced by hallucinogenic drugs such as lysergic acid diethylamide and mescaline, as well as in some clinical cases of dissociation syndromes of schizophrenic pattern. Although the neurophysiological, neurochemical, and neuropharmacological mechanisms behind the clinical results obtained with these drugs await explanation, it would appear that the door has been opened, that further compounds of this type will be forthcoming, and that an understanding of their mode of action may be reached. A word to describe this new order of pharmacological effects appears to be justified. "Tranquilizing agents," a term used descriptively thus far, does not entirely fill the bill, nor are such words as "anti-hallucinogens" adequate. Alister Cameron, professor of classics, University of Cincinnati, has suggested that the Greeks had a word for it. The adjective *ataraktos* meant without confusion, cool, and steady, and the noun *ataraxia* meant freedom from confusion and peace of mind. Cameron tells me that the Epicureans were especially fond of this term, that they almost had a patent on it, and that it represented one of the prime goals of their philosophical system. The term was taken over in its entirety into Latin as *ataraxia*. In English it is ataraxy, and the definition given in the Revised Shorter Oxford Dictionary is "freedom from disturbance of mind or passion." It is my proposal, therefore, that drugs of this type be designated "ataraxics" and that the adjective form "ataractic" be used to describe this therapeutic property in drugs.

RESIDENCIES FOR RADIOLOGY

To the Editor:—In collaboration with the Joint Residency Review Committee for Radiology, representing the American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association, the American Board of Radiology has adopted the following policy.

"Effective immediately, hospitals and institutions making initial application for approval for residency training in radiology must qualify for full three-year approval. No new residencies of one or two years' duration will be approved unless they are integrated with or contributory to a fully approved program. It is strongly recommended that all hospitals and institutions presently approved for residency training in radiology develop programs offering complete training, either intramurally or through affiliation by June 30, 1957."

The Joint Residency Review Committee has been established to act in behalf of these two organizations in approving residency programs in this specialty. The present policy relating to future approval for full training only has been adopted to insure that residents receive integrated training with graded responsibility and continuity of supervision during their three years' residency. The requirement of a fully organized program in qualifying for approval is in accord with sound educational principles as adopted in several other specialty fields. The committee does not believe it to be in the best interest of the resident that he be permitted to take a year or more of isolated training in two or three unrelated programs in qualifying for board examination. Residents who have accepted appointment to programs that are presently approved for less than three years will receive full credit for their training on the basis of the residency's present status, through June 30, 1957.

Secretary-Treasurer
American Board of Radiology
Kahler Hotel Building
Rochester, Minn.

THE FAMILY PHYSICIAN

To the Editor:—In The Journal, June 18, page 535, is an article by Dr. Emil Seletz on recent trends in management of craniocerebral injuries. In it are several remarks directed against the general practitioner, who, in most cases, is the "family physician." If this is the type general practitioner Dr. Seletz has had the opportunity of meeting, it is most regrettable. It seems possible he may have created a general practitioner of such caliber to lend emphasis to his article. No doubt a certain percentage of general practitioners fit his description. I feel assured the percentage is small. As general practitioners, we forgive Seletz for his lowly opinion of us. We are doing our job to the best of our ability. I have often remarked I would not want to practice medicine without having specialists available. Most of us do seek the assistance of specialists whenever the need arises. I am sure it is usually in sufficient time and quite often with the correct diagnosis accompanying the patient. At least we recognize the need for a specialist's diagnostic ability in his particular field. Inasmuch as lay individuals in all walks of life have access to and read The Journal, it is evident that such material can bring discredit to the general practitioner. Such attacks from within our own ranks are folly. I believe that Dr. Seletz should be advised his remarks are not desirable. I also feel it should be suggested to the American Medical Association that such articles be rejected or revised to avoid further discredit to the medical profession.

JOURNALS TO FORMOSA

To the Editor:—I have been asked by Dr. C. S. Huang, director, Taiwan Provincial Shikau Mental Hospital, 138 Hu-lin Street, Shun-san, Taipei, Taiwan (Formosa), for help in securing up-to-date material. His hospital is the only mental hospital for the 9 million people in Taiwan. He wrote me a pathetic letter concerning the "old methods," and the need to get his hospital "improved." My acquaintance with Dr. Huang developed through correspondence regarding a shock therapy machine that I was able to send through the generosity of the women of Lincoln, Neb., following a visit to Taiwan with my husband. The Taipei Women's Club asked me to try to get the machine. It was received with the greatest appreciation. Do you know who might send complimentary subscriptions of current journals?

Mrs. R. G. Simmons
2927 Plymouth
Lincoln, Neb.

GOVERNMENT SERVICES

ARMY

Higher Entrance Rates for Civilian Physicians.—The Civil Service Commission has granted authority to employ civilian physicians at dispensaries, infirmaries, outpatient clinics, and laboratories at the top step of each respective grade, according to Major Gen. Silas B. Hays, the surgeon general. The new authority, which goes into effect immediately, allows the Army to employ civilian physicians at beginning salaries from $7,465 per annum to $11,395 per annum. Although increasing numbers of civilian doctors are being employed in Army medical installations throughout the country, openings exist in practically every locality. As of June 30, according to General Hays, the Army was employing over 20% more civilian physicians than it had six months earlier. Those interested in securing employment with the Army and who have a license to practice medicine in any of the states or the District of Columbia should get in touch with the personnel officer at their nearest Army installation or Army medical facility of their choice.

VETERANS ADMINISTRATION

Mental Hygiene Clinics.—The Veterans Administration operates 62 mental hygiene clinics throughout the country, of which 39 are in regional offices, 14 are in hospitals, and 9 are in smaller VA offices. The VA also operates one traveling clinic. In addition, the VA uses the services of 46 contract clinics, most of them state or community agencies. About one-fourth of the patients come to VA clinics on their own. Another fourth are referred by other medical divisions of the VA's regional offices. About one-eighth are referred by VA contact representatives, and the remainder come from community clinics, social agencies, and the like. In addition to their role as a treatment agency, the clinics play a part in training and provide an important resource for the development of clinical skills by psychiatrists, clinical psychologists, and social workers. The clinics further furnish the framework for significant research in psychiatry and clinical psychology.

The VA claims that these mental hygiene clinics keep an average of 2,200 mentally sick veterans out of hospitals every year. A great number of these veterans are engaged in useful, productive work while receiving treatment and generally improve sufficiently to end their outpatient treatments. Only veterans with service-connected neuroses or psychoses may be treated in the VA's mental hygiene clinics. The law does not permit the treatment of non-service-connected cases on an outpatient basis.

Training Program in Rehabilitation.—The Veterans Administration has launched a residency training program in physical medicine and rehabilitation for its full-time career physicians. Prior service in the VA will not be a requirement for this training as long as the obligated service contract is signed. Formal residency training will be provided at VA hospitals approved for such training by the American Medical Association and the American Board of Physical Medicine and Rehabilitation. Five VA hospitals have been designated to put this program into effect on a pilot basis. The hospitals are in Boston; the Bronx, N. Y.; Hines, Ill.; Houston, Texas; and Los Angeles. Selection of VA physicians will be restricted to physicians in intermediate or lower grades. To be eligible, physicians also must be approved by the manager and the deans committee of the training hospitals concerned. Contracts with physicians selected for this training will require that: for one year served in training, the obligated service shall be one additional year; for two years served in training, the obligated service shall be one and one-half additional years; for three years served in training, the obligated service shall be two additional years. Application should be sent to the manager of the VA hospital in which the physician wishes to take his residency training.

Changes in Hospital Managers.—Appointment of managers for Veterans Administration hospitals at Minot, N. D., and Lebanon, Pa., have been announced. Dr. Roland W. Hipsley, manager of the Minot hospital, has been transferred in the same position to the 1,065-bed hospital at Lebanon, succeeding Dr. James R. Glotfelty whose transfer to the VA hospital at Durham was announced recently.

Personal.—Dr. Fred M. Patterson, Greensboro, N. C., has been appointed examining physician, chief grade, in the VA regional office in Columbia, S. C., and will assume his duties about Aug. 15.

PUBLIC HEALTH SERVICE

Allocation of Poliomyelitis Vaccine.—The voluntary plan for allocation of poliomyelitis vaccine, under which the states and territories will have the responsibility for its distribution, both through commercial and public agency channels, has gone into effect, the Department of Health, Education, and Welfare, announced, after the National Foundation for Infantile Paralysis announced that its immediate summertime needs had been met and that it would not require all of the last batch of poliomyelitis vaccine released for use. Under the voluntary plan each new batch of the vaccine will be allocated among the states as it becomes available. The states will then determine what proportion of their share is to go to public agencies and what amount will be distributed by the manufacturers through normal drug channels for use by private physicians.

Allocations to the states will be based on each state's proportion of children in the initial priority group, excluding children who have already been immunized under the program of the National Foundation for Infantile Paralysis. The current priority age group of five through nine was recommended by the National Advisory Committee on Poliomyelitis Vaccine in May. For the country as a whole, these children are in the age group most susceptible to poliomyelitis. The department also announced the first allocation to the states, consisting of 846,000 cc. of vaccine. This is the amount remaining from the last batch of vaccine released by the Public Health Service after the current needs of the foundation had been met. Within all the states, officials have been designated by the governors to handle the problems of equitable intrastate distribution. The foundation's announcement that its immediate summertime program will not require additional vaccine said that the manufacturers have agreed to make available some 3 million cc. of the vaccine in the fall so that the foundation can resume distribution of vaccine for immunization of children in the first and second grades in those states that have halted immunization for the summer.

Manual of Tests for Syphilis.—The Public Health Service has announced release of the 1955 edition of the Manual of Serologic Tests for Syphilis, which assembles the latest technical procedures to be observed in the performance of each of the reliable, evaluated serologic tests for syphilis now commonly employed in the U. S. Earlier editions have proved effective in developing the high degree of standardization of serologic testing procedures now evident in laboratories throughout the nation. The 106-page manual (Public Health Service Publication No. 411) is especially designed for use in laboratories. Copies may be obtained from the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. The price per single copy is $1.00.

Monkeys for Research and Production of Antipoliomyelitis Vaccine.—As a result of negotiations, the United States Mission t India and the United States Embassy in India have secured th agreement of the government of India to permit the continue exportation of rhesus monkeys for medical research and production of antipoliomyelitis vaccine. All needs must be certified b the U. S. government through the Public Health Service. Information concerning Public Health Service procedure and Certificate of Need forms may be secured from: National Institute of Health, Room 1012, Building T-6, Bethesda 14, Md. (Telephone number: OLiver 6-4000, Ext. 2748, Miss Parent).

COUNCIL ON INDUSTRIAL HEALTH

The following text and tables are abstracted from a lengthier presentation to be issued separately by the Council on Industrial Health. The complete report will contain comprehensive data for 39 jurisdictions, covering both annual and 10 year base periods. Pertinent data relating to medical relations in workmen's compensation together with a number of fee schedules will be incorporated. C. M. PETERSON, M.D., *Secretary.*

SOME MONETARY ASPECTS OF WORKMEN'S COMPENSATION EXPERIENCE IN THIRTY-NINE JURISDICTIONS

A substantial deficiency in pertinent literature of the past has been the lack of comprehensive information on the trend of dollar losses incurred for indemnity and medical benefits under workmen's compensation. To meet this need, at least partially, the Council on Industrial Health has undertaken this study to provide the medical profession with a source book of factual information in practical nontechnical form on: (1) incurred losses for indemnity and medical benefits, (2) distribution of the premium dollar, (3) selected statutory and administrative provisions that may affect losses incurred, and (4) official medical fee schedules and related directives. Premiums earned are also included, since this is the factor to which losses incurred are usually compared.

The selection of the 39 jurisdictions included in this study was governed solely by the availability of uniform statistical material from the most authoritative source. This source is the National Council on Compensation Insurance, which provided statistical tables by policy years for each jurisdiction on premiums earned, total number of compensable and noncompensable cases, total indemnity losses incurred, and total compensable and noncompensable medical losses incurred. Since the National Council is the official statistical agency of the insurance industry and the great majority of compensation insurance carriers report to it, the material supplied by this organization should be considered a comprehensive and accurate reflection of workmen's compensation experience in these jurisdictions. The National Council on Compensation Insurance compiled this information for the latest 10 year period wherever available. No comparable information is available for the seven jurisdictions with exclusive state insurance funds nor for the four that do not report to the National Council; nor is comparable and adequate information available from self-insurers in any jurisdiction. It is recognized that the inclusion of such information would enhance the value of this study. The Council on Industrial Health hopes to prepare supplemental studies in these areas in the future. Meanwhile, it believes that the material contained herein is competent for the purposes of this study.

Because much of the material in this study has been adapted from a number of recognized sources, these sources and a glossary have been listed in a separate section in lieu of extensive and repetitious footnotes. To avoid interspersing these in the text, all statistical tables have been placed together in a separate section, as have the official fee schedules and directives. This study is not intended to provide evaluations and comparisons of experience in individual jurisdictions. Such studies can best be made at the local level and on a regional basis; however, a few general comments can be made on the over-all picture as developed in this study.

GENERAL COMMENTS

With the exception of 1951, workmen's compensation has been a profitable business for the insurance industry from 1936 to date. In 1947, 1948, and 1949 workmen's compensation led all other casualty insurance lines in dollar profit. According to *Best's Insurance Reports* the remarkably good underwriting in these three years set the stage for rate decreases just at the time another round of inflation forced up medical and hospital costs. This combination of factors resulted in a temporary lapse into the red in 1951. The data in this study clearly indicate that medical losses incurred during base periods in all jurisdictions have increased substantially in dollar amounts, as have premiums earned, total losses, and indemnity incurred.

The question of vital interest to everyone is, of course, whether medical losses incurred have and are increasing disproportionately to premiums earned and indemnity losses incurred. The limitations of this study do not permit a general answer to this question; however, an analysis of each jurisdiction, as presented in this compilation and combined with other appropriate factors, should provide partial clues. Among the factors that should be considered in making such a value judgment are changes in statutory or administrative provisions related to medical aid and indemnity occurring during the base periods, as well as insurance coverage and rates.

The quality of medical services cannot be judged solely on the basis of dollar amounts incurred or paid for either indemnity or medical benefits for temporary or permanent disability. All too often this obvious fact is acknowledged and is then followed by an evaluation based largely, if not entirely, on these very standards. The preferred basis for evaluating the quality of medical services and the medical aid program includes the scope and volume of care, the degree of coordination of different services, and their continuity, timeliness, and balance that result in maximum rehabilitation of the disabled employee. Payments for medical benefits form by far the largest flexible expenditure in a workmen's compensation system because: (1) indemnity payments are fixed by statute and are supervised by the administrative agency, and (2) the portion of the premium to be retained by the carriers is also fixed at a point that is supposed to cover the expense of securing and conducting the business and to provide for an underwriting profit. It appears likely that any surplus obtained by the carriers must come largely from ability to keep the expense of medical benefits below the level at which it is estimated for the purpose of rate-making and through the selection of risks, accident prevention, and adjustment of schedule and experience variations.

An article by Bram Cavin,[1] associate editor, in the September, 1953, issue of the *Casualty and Surety Journal* provided the following basic breakdown of the workmen's compensation premium dollar:

	Cents
Loss and loss adjustment expenses	65.5
Inspection, exposure audit, and bureau	4.5
General administration	7.5
Production cost	17.5
Taxes, licenses, fees	2.5
Underwriting profit and contingencies	2.5

Mr. Cavin stated: "The table on page 6 shows the breakdown of the insurance dollar for the different lines of casualty insurance. While the figures may vary from year to year, over a great many years the variations average out and the proportions of the premium dollar allocated to the various function are as indicated. There are also minor variations from the table in some states, but, on the whole, the table represents the basic breakdown of the premium dollar." Although not included in Mr. Cavin's article, loss and loss adjustment expenses for a number of years have been allocated approximately in the following manner:

Loss and loss adjustment expenses		100% (65.5 cents)
Indemnity	59% (38.3 cents)	
Medical	29 (19.2 cents)	
Claim adjustment expense	12 (8.0 cents)	

---

‡ x in column, 1—physician may be selected by employee; 2—medical benefits limited in time and/or amount; 3—official fee schedule; blanks—physician selected by employer, unlimited medical benefits, and no official fee schedule.

The principal source available on the distribution of medical losses in workmen's compensation is the annual reports of the Bureau of Employees' Compensation for fiscal years 1941-1952. This agency administers the Federal Employees' Compensation Act in all workmen's compensation jurisdictions, including those in this study. No fee schedule is used by the bureau except in those jurisdictions where one is officially recognized in other compensation cases. The statistical table section of this study contains the annual distribution of the bureau's medical losses for the fiscal years 1941-1952. As may be seen from this table the average distribution for this period was:

Physicians and surgeons	31%
Hospitals	60
Other services (nursing, appliances, drugs, etc.)	9

It may reasonably be assumed that trends, at least, can be established by the application of appropriate percentages to medical losses incurred in other workmen's compensation cases. For example, the average medical loss incurred in a given jurisdiction for the fiscal years 1941-1952 might be $50. By applying the bureau's data to this amount, $15.50 would be allocated for physicians' and surgeons' services, $30 for hospitals, and $4.50 for other services. If the average medical share of the earned premium dollar for a similar period was 18.4 cents, approximately 6 cents would be allocated for physicians' and surgeons' services, 11 cents for hospitals, and 2 cents for other services. It is interesting to note that in 14 of the jurisdictions included in this study the amount incurred for medical losses does not equal the amount allocated for production (acquisition of business) costs. This fact is especially noteworthy in the seven jurisdictions where the law is compulsory.

While physicians' and surgeons' fees are frequently regarded as responsible for increased medical losses incurred, this is not borne out by the experience of the federal Bureau of Employees' Compensation. The percentage of medical losses for physicians' and surgeons' fees has declined from 49% in 1941 to 25% in 1952, with a low of 22% in 1945 and 1950. Hospitalization has absorbed an increasing amount, ranging from 40% in 1941 to 65% in 1952, with a high of 72% in 1945. The amount for other services has varied from 11% in 1941 to 10% in 1951, with a high of 14% in 1946. It is generally thought that minimal medical losses incurred, and indirectly indemnity, are more probable when the employer or carrier has the right of physician selection. Medical benefits limited in time and/or amount and official fee schedules are also considered "controlling factors." The data in this study and several tests applied to them seem to prove conclusively that this is a misconception (table 3). There is no apparent relation between low dollar amounts for medical losses incurred and any one or combination of the three "controlling factors." Nor do these "controlling factors" appear to affect any upward trend in medical losses incurred. Indeed, there are definite indications that the contrary may be true.

Various workmen's compensation administrative agencies provided the Council with copies of official fee schedules and related directives for the information of the medical profession. These and all other tables are presented as factual material. No endorsements or unfavorable comparisons between jurisdictions by the Council have been intended or should be implied. If this study stimulates a more thorough understanding of some monetary aspects of workmen's compensation, it will have served the purpose for which it was intended by the Council on Industrial Health.

MEDICINE AND THE LAW

BLOOD TRANSFUSION—SALE OR SERVICE

The Uniform Sales Act has been adopted *in toto* or in substance in almost every state. The statutory provisions contained therein are, in most particulars, a codification of business practices that developed under the Common Law and under custom and usage in Common Law jurisdictions. This act provides, among other things, that if a buyer makes known to a seller, either expressly or by implication, the particular purpose for which the goods sold are required and if it then appears that the buyer relies on the special skill or judgment of the seller in furnishing these goods, there will exist an implied warranty that the goods shall be reasonably fit for the purpose indicated. This warranty, plus a warranty that the goods shall be of merchantable quality, exists under the laws of the state of New York.[1] In a recent case decided by the Court of Appeals of New York,[2] the plaintiff attempted to apply this warranty concept to a blood transfusion.

In her complaint, the plaintiff alleged that while she was receiving medical care and treatment as a pay patient in the Beth David Hospital, she received a blood transfusion; that the blood used in the transfusion was sold to her by the hospital for $60; that the hospital knowing the purpose for which the blood was to be used and upon whose "skill and judgment" the plaintiff "relied," warranted by implication that the blood was "fit" for such intended purpose, was of "merchantable quality," was pure and harmless, and contained no injurious substances, agents, viruses, germs or impurities. The plaintiff further alleged, however, that the blood was not fit or of merchantable quality; it contained jaundice viruses, and she became afflicted with homologous serum jaundice. The plaintiff sued for damages resulting from the transfusion, not on grounds of negligence, but on the theory that the supplying of blood for the transfusion was a sale of blood from the hospital to her and was subject to the implied warranty previously mentioned.

Was there, asked the Court of Appeals, a vendor-vendee relationship between the hospital and the plaintiff, one of its pay patients? To answer this question, the court first found it necessary to consider the true function of a hospital and the true relationship existing between a hospital and its patients. A hospital, said the court, is devoted to the care and healing of the sick. Not only does it gather in its wards "a company of skilled physicians and trained nurses" and place their services "at the call of the afflicted" but it also offers to patients "the benefit of facilities" and equipment, developed through medical science, "that would not otherwise be available." The essence of the contractual relationship between hospital and patient is readily apparent; the patient bargains for, and the hospital agrees to make available, the human skill and physical materials of medical science to the end that the patient's health be restored. Concepts of purchase and sale cannot separately be attached to the healing materials—such as medicines, drugs, or blood—supplied by the hospital, for a price, as part of the services it offers. That the property or title to certain items of medical material may be transferred, so to speak, from the hospital to the patient during the course of medical treatment does not serve to make each such transaction a sale. "Sale" and "transfer" are not synonymous, and not every transfer of personal property constitutes a sale. When service predominates and transfer of personal property is but an incidental feature of the transaction, the transaction is not deemed a sale within the Uniform Sales Act.

The supplying of blood by the hospital was entirely subordinate to its paramount function of furnishing trained personnel and specialized facilities in an endeavor to restore the plaintiff's health. It was not blood—or iodine or bandages—for which the plaintiff bargained, but for the knowledge of the hospital staff and the availability of hospital facilities to provide whatever medical treatment was considered advisable. The conclusion is evident that the furnishing of blood was only an incidental and a secondary adjunct to the services performed by the hospital and, therefore, was not within the provisions of the Uniform Sales Act. The fact that the treatment might have come from a physician, while the blood came from the hospital, is of no operative consequence; it is the transaction regarded in its entirety that must determine its nature and character. In further support of its conclusion, the Court of Appeals noted, by way of analogy, that a contract to paint a picture is not a sale o a piece of canvas, a contract to construct a highway is not a sale of gravel, a contract by an optometrist to test and prescribe glasses is not a sale of eyeglasses, and rendering of care by a dentist is not a sale of crowns or false teeth.

Having, therefore, determined that the furnishing of blood for a transfusion is a service rather than the sale of a commodity, the Court of Appeals went on to speculate a little bi on how the contention of the plaintiff, if sustained, would affec the liability of a physician and hospital. If, said the court, th supplying of blood—or the furnishing of any other medica aid—by a hospital is said to be a sale, it would mean that th hospital, no matter how careful, no matter that the disease producing potential in the blood could not possibly be discovered, would be held responsible, virtually, as an insurer, i anything happened to the patient as a result of "bad" blood.

According to the complaint, the blood administered to th plaintiff was "contaminated" with jaundice viruses, with th result that she was afflicted with homologous serum jaundic *Informed opinion states that there is neither* a means of detecting the presence of the jaundice-producing agent in a donor' blood nor a practical method of treating the blood to be use for transfusion so that the danger may be eliminated. Whethe that is so, it is a fact that, if the transaction were to be deeme a sale, liability would attach irrespective of negligence or othe fault. The art of healing frequently calls for a balancing of risk and dangers to a patient. Consequently, if injury results from the course adopted, where no negligence or fault is present liability should not be imposed upon the institution or agenc actually to save or otherwise assist the patient.

The Court of Appeals accordingly concluded that the use o blood for a blood transfusion in a hospital did not constitut the sale of blood to the patient by the hospital and that th patient was therefore not entitled to recover damages from th hospital for injuries sustained as a result of the use of contaminated blood.

[2] *Perlmutter* v. *Beth David Hospital,* 123 N.E. (2d) 792.

Mitral Valvuloplasty.—A study is reported of various factor that affect the late results in patients with mitral stenosis operated by mitral valvuloplasty. This study is based chiefly on a follow-up of the first 500 patients. Seventy-eight per cent of the patients surviving operation showed significant and usually persistent improvement over the period of observation, which averaged 22 months. The factors which led to good results were (1) age over 40; (2) auricular fibrilation; (3) associated aortic valve disease; (4) associated mitral insufficiency of moderate degree or more; (5) a preoperative valve size of more than 1.0 sq. cm.; (6) a postoperative valve size of less than 2.5 sq. cm. (7) calcification of the mitral valve. Even in the less successful categories the over-all results were still good in a majority of the patients. Poor late results occurred in direct proportion to the number of adverse factors present. . . . The procedure appears to protect substantially against late peripheral embolization, although the incidence of operative emboli is somewhat greater in patients who have had previous emboli than in the groups as a whole. Good end results depend on intelligent and careful selection of patients and on the quality of the valvuloplasty performed by the surgeon.—L. B. Ellis, M.D., and D. E. Harken, M.D., Factors Influencing the Late Results of Mitral Valvuloplasty for Mitral Stenosis, *Annals of Internal Medicine,* July, 1955.

Cardiac Hypertrophy and Insufficiency of Unknown Etiology: A Clinical and Pathologic Study of Ten Cases. S. K. Elster, H. Horn and L. R. Tuchman. Am. J. Med. 18:900-922 (June) 1955 [New York].

The authors collected from the 1937 to 1952 postmortem files of the Mount Sinai Hospital of New York the records of all patients with enlargement of the heart. Their aim was to find cases that could not be ascribed to the usual causal factors. They found 10 patients with cardiac hypertrophy and myocardial failure in whom conventional etiological factors, such as rheumatic fever, hypertension, syphilis, arteriosclerosis, bronchopulmonary disease, and congenital abnormalities, were excluded. The clinical course of these patients was rapidly progressive and fatal, and frequently complicated by recurrent pulmonary and systemic thromboembolism. At autopsy the hearts showed striking hypertrophy. Degenerative muscular changes, focal necrosis, and patchy fibrosis were found predominantly subendocardially and endocardially, frequently associated with mural thrombosis. There were no significant abnormalities of the pericardium, coronary arterial tree, cardiac valves, or aorta. A brief review of similar cases previously described is presented, but none of the causes heretofore suggested as primarily responsible for this syndrome are believed by the authors to have been established. Myocardial anoxia, a concomitant of the marked hypertrophy and dilation, is believed to be an important factor in the intensification of the intracardiac abnormality. The authors believe that this entity should be considered in all patients with cardiac hypertrophy in whom the usual causes cannot be established.

The Relationship Between Renal Blood Flow, Glomerular Filtration Rate and Sodium Excretion, Cardiac Output and Pulmonary and Systemic Blood Pressures in Various Heart Disorders. L. Werkö, J. Ek, E. Varnauskas and others. Am. Heart J. 49: 823-837 (June) 1955 [St. Louis].

The cardiac output and blood pressures in the pulmonary and systemic circulation were determined simultaneously with the renal clearances for inulin and *p*-aminohippurate in 146 patients with various heart disorders. Of the 146 patients, 34 had congenital heart disease, 7 primary pulmonary disease, 4 constrictive pericarditis, 2 polycythemia, 15 hypertensive cardiovascular disease, 12 aortic valvular disease, and 72 mitral valvular disease. The same values were determined both at rest and during exercise in most patients. In some patients the study was repeated after surgical correction of the heart lesion. In some patients determinations were repeated several times during the intravenous infusion of isotonic dextrose solution at a rate of about 25 cc. per minute. The renal blood flow was lower than normal in all patients with cardiovascular disease, roughly proportional to the severity of the heart disease. The decreased renal blood flow was usually observed together with decreased stroke volume, but elevated renal venous pressure seemed to contribute to the decreased blood flow not at all or only a little. Studies during exercise also pointed to the minor importance of the elevated venous pressure for the renal changes. The renal blood flow increased to normal when a patient with patent ductus arteriosus underwent surgical correction and toward normal in a patient with auricular septal defect and pulmonary stenosis when the defect was closed. When patients with mitral stenosis were operated on, the renal blood flow showed variable changes, although a slight increase usually was observed when the pulmonary circulation was improved. When isotonic dextrose was infused rapidly, the renal blood flow increased to normal in patients with mitral stenosis or pulmonary fibrosis. The sodium excretion increased successively to several times the basal value. This reaction was observed likewise in patients with arterial hypertension but not in normal persons. The authors' observations indicate that patients with heart disease prone to develop congestive failure, long before any signs of failure have appeared, exhibit changes in renal circulation and altered sodium handling by the kidneys.

Ventricular Aneurysms of the Heart: Preliminary Report on Some New Clinical Signs. R. J. Vakil. Am. Heart J. 49:934-937 (June) 1955 [St. Louis].

In a recent study of 20 patients with proved ventricular aneurysm of the heart the following clinical signs, hitherto undescribed in the literature, were discovered. Of the 20 patients, 10 had an anomalous location of the cardiac impulse. A very wide or diffuse systolic thrust or pulsation, forcible and heaving in character, was observed and felt at the level of the fourth left intercostal space, halfway between the left parasternal and midclavicular lines. Thirteen patients had a myotonic cardiac impulse; four a double thrust or reduplicated impulse; six a wavy impulse or cardiac shudder; two a heaving, up-and-down movement of the left costal margin; nine a stony dulness over the precordium; and five a loud, long, musical, or "cooing" systolic-diastolic murmur. These signs, which are likely to facilitate recognition of ventricular aneurysm during life, are briefly described in the hope of stimulating further investigation.

Diabetes Insipidus: Discussion, Including Reexamination of the Site and Mode of Action of the Antidiuretic Hormone. A. G. White. J. Mt. Sinai Hosp. 22:15-23 (May-June) 1955 [New York].

Of 219 cases of diabetes insipidus 23.3% were primary and 76.7% secondary to some detectable disease. The essential symptoms of diabetes insipidus are excessive thirst, polyuria, and the excretion of urine of low specific gravity. Other signs and symptoms depend on: (1) the underlying disease, where one exists, and (2) the supervention of dehydration that occurs in the untreated patient when the intake of fluids does not keep pace with the output. It is generally agreed that the excessive thirst is secondary to the polyuria, but this does not exclude the possibility that excessive thirst may occur as a primary symptom after trauma or disease of the central nervous system. Data are cited to suggest that the antidiuretic hormone may act not only on the distal portion of the renal tubule, as postulated hitherto, but also on the proximal tubule of the nephron by altering the osmotic activity of solutes so that they carry along with them at least twice as much water in the patient with diabetes insipidus as they would during diuresis in hydropenic subjects.

Fat Embolism in Diabetic Patients Without Physical Trauma. S. P. Kent. Am. J. Path. 31:399-403 (May-June) 1955 [Ann Arbor, Mich.].

Fat embolism is usually thought of as related to trauma, especially traumatic fractures of bones, but fat embolism has been reported in patients with various diseases unrelated to trauma, particularly in diabetic patients. To determine whether the fat emboli found in diabetic patients could be distinguished from those found in traumatic cases, and whether the sustained

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

lipemia often associated with diabetes mellitus predisposes such patients to the development of fat emboli, the lungs of 53 diabetic patients who had not received known physical trauma within three weeks of death were examined for fat emboli. Fifty-three consecutive, nontraumatic, nondiabetic patients served as controls. Fat emboli were found in 24 of 53 diabetic patients, and the control series included 11 persons with emboli. Thus while fat emboli were found in both groups, the percentage of patients with fat emboli was much higher in the diabetic group. The fat emboli were usually few in number in those patients who had them and were probably of no clinical significance. They could not be differentiated from fat emboli found in patients with trauma. The five diabetic patients who had more abundant emboli were all in poor metabolic control. Four died in diabetic coma. The other patient was admitted in hypoglycemic shock and died a few hours later. These five probably had lipemia of some degree, as lipemia is usually more common and more severe in poorly regulated diabetic patients. The higher incidence of fat emboli in this limited series of diabetic patients does not necessarily implicate lipemic serum as the source of the fat emboli in these patients.

Regurgitation Type of Jaundice During Prolonged Therapy with Chlorpromazine. R. E. Lemire and R. A. Mitchell. A. M. A. Arch. Int. Med. 95:840-845 (June) 1955 [Chicago].

While receiving chlorpromazine therapy for various reasons, three patients showed protracted jaundice with laboratory findings compatible with obstruction of the extrahepatic biliary tract but with no systemic manifestations except pruritus. The liver was palpable in only one patient. All had hyperbilirubinemia, elevated alkaline phosphatase, and normal cephalin-flocculation determinations. Evidence of probable mild parenchymal damage was noted in the slight elevation of the thymol turbidity in one and in the serum globulin in two of the patients. Cholesterol determinations in two of the patients gave normal findings in one and hypercholesterolemia with decrease in the cholesterol esters in the other. Surgical jaundice could not be excluded by laboratory or clinical studies, and all three patients underwent operation, with no findings of obstruction in two. In the third patient the prior existence of a transitory stone in the common bile duct could not be completely excluded. Liver biopsies in two patients showed inflammatory cell infiltration within the lobule, minimal liver cell changes, and bile plugging of the bile canaliculi. There was a slight increase in the cellularity of the portal triads, with no evidence of obstruction of the larger biliary channels. The mechanism of this complication is unknown.

Posthepatitic Syndrome. L. Kallai. Gastroenterologia 83:77-99 (No. 2) 1955 (In English) [Basel, Switzerland].

Of 42 patients with hyperbilirubinemia, 31 had a history of previous manifest hepatitis, while in the remaining 11 such data were lacking. The clinical aspect of the 42 patients was characterized by a chronic or intermittent jaundice accompanied by subjective symptoms such as fatigue, exhaustion after work, pain below the right costal margin, nausea, lack of appetite, and loss of weight. The only abnormal finding was a more or less marked steatosis. The great similarity of symptoms and of the biochemical and microscopic findings in those patients with the posthepatitic syndrome and those with so-called chronic hyperbilirubinemia was striking. Since the posthepatitic syndrome cannot be differentiated from so-called chronic hyperbilirubinemia, one may assume that the latter condition is a complication or sequela of the anicteric form of infectious hepatitis.

Clinical Studies of Triethylenethiophosphoramide in the Treatment of Inoperable Cancer. H. Shay and D. C. H. Sun. Cancer 8:498-511 (May-June) 1955 [Philadelphia].

Triethylenethiophosphoramide (thio-TEPA) is a new nitrogen-mustard-like compound that can be administered intramuscularly, intravenously, or locally into tumor nodules without any immediate untoward effects. It was given to 47 patients with inoperable recurrent or metastatic cancer no longer suitable for surgery or responsive to roentgen ray and/or other therapy. The 12 patients with carcinoma of the breast had been treated initially with radical or simple mastectomy, and when recurrences or metastatic lesions developed, they usually responded temporarily to combined roentgen ray, testosterone, and/or castration therapy. After that thio-TEPA was tried. Six of these patients experienced regression of enlarged nodes and tumor nodules that continued for 2 to 12 months; four showed no definite improvement; and the remaining two did not receive enough thio-TEPA to warrant an evaluation of its action. Two of three patients with carcinoma of the ovary, and each of two patients with widespread malignant melanoma showed temporary regression on treatment with thio-TEPA. Only slight or no improvement from thio-TEPA therapy was observed in seven patients with carcinoma of the lung, two with carcinoma of the larynx, three with carcinoma of the esophagus, four with carcinoma of the stomach, two with carcinoma of the colon, three with carcinoma of the sigmoid, four with carcinoma of the rectum, one each with carcinoma of the small intestine, prostate, thyroid, and biliary tract, and one with malignant hepatoma. During administration of thio-TEPA, leukocyte counts should be made daily and a complete blood count including a platelet count weekly. Injections of thio-TEPA should be given daily if conditions permit. The size of any one dose and the intervals between the injections are guided by the hematological response. The following dosage schedule seems to be safe. One milligram of thio-TEPA is given intravenously for every 1,000 white blood cells. The maximum dose for any single daily injection should not exceed 10 mg. If the leukocyte count is 3,500 per cubic millimeter or less, no drug is given. Should the platelet count drop to 150,000 per cubic millimeter, or should there be a sudden drop in the erythrocyte count and hemoglobin level, thio-TEPA should be withheld and a bone marrow aspiration done. In patients with roentgenographic or other evidences of bony metastasis or in patients with infection, thio-TEPA should be given with caution. Bone marrow studies should be made fairly frequently, and if the marrow aspirate is hypocellular the therapy should be discontinued until another bone marrow aspirate shows a normal cellular activity.

Triethylenethiophosphoramide in the Treatment of Chronic Leukemia. C. J. D. Zarafonetis, H. Shay and D. C. H. Sun. Cancer 8:512-522 (May-June) 1955 [Philadelphia].

Nine patients with chronic granulocytic leukemia and two with chronic lymphocytic leukemia were treated for intervals up to 20 months with triethylenethiophosphoramide (thio-TEPA). Clinical and/or hematological remissions were induced in all of the subjects but were of varied duration despite continued therapy. The drug was effective whether administered orally, intravenously, or intramuscularly. For intravenous or intramuscular administration it was dissolved in sterile physiological sodium chloride solution in a concentration of 10 mg. per cubic centimeter. It was then passed through a sintered glass filter, tested for sterility, and stored in rubber-capped vials at 4 C. The usual parenteral dose was 2 to 10 mg., but as much as 25 mg. was given on occasion. For intravenous therapy the stock solution was further diluted in 10 cc. of sterile isotonic sodium chloride solution. Later this step became optional, as it was found that the 10 mg. per cubic centimeter concentration of thio-TEPA gave no local irritation either on intravenous or intramuscular injection. Tablets for oral administration were provided in 5-mg. and 10-mg. sizes. Patients received thio-TEPA by injection or in tablet form, usually daily at first and later at longer intervals, depending on the hematological findings during the course of treatment. All of the subjects had complete pretreatment blood examinations and, with one exception, pretreatment bone marrow studies. Blood studies were repeated almost daily, and bone marrow aspirations were repeated at appropriate intervals throughout treatment and during the follow-up period. Temporary bone marrow depression was observed in eight of the patients, but no other untoward side-effects were observed. Thio-TEPA is of value in the management of chronic leukemia.

Local Treatment of Tuberculous Empyema and Colliquative Tuberculosis of Soft Tissue Parts. F. Muhar. Wien. med. Wchnschr. 105:395-396 (May 14) 1955 (In German) [Vienna, Austria].

A new proprietary preparation, "Substance VI," an amide of *p*-methylbenzenesulfonic acid, was used on 23 patients with tuberculous empyema and 60 patients with colliquative tuberculosis of the skin. In the patients with empyema, the empyema cavity was irrigated with a 1% solution of Substance VI, and after removal of fluid by puncture, irrigation was repeated two to three times, and then 200 to 300 cc. of the solution were left in the empyema cavity for two or three hours. In one patient with a particularly thick-walled empyema pocket, 500 cc. of 1% solution of Substance VI were left in the cavity for 24 hours. The patient was under constant control since hemolysis had been observed in blood slides with a concentration of 0.3% or more of Substance VI. The cavity in this patient was sterilized within 24 hours, but as a rule the drug was left only for three hours in the cavity in order to prevent complications. Four of the 23 patients received local treatment with Substance VI exclusively, and the other patients were given streptomycin, amithiozone, *p*-aminosalicylic acid, and later isoniazid orally or parenterally in addition to local treatment with Substance VI for a short time at least. In the course of local therapy with Substance VI the exudate turned watery and the cavity became smaller in size until it disappeared completely. In two patients, however, the exudate remained purulent and thick, although the size of the cavity became smaller; the residual cavity disappeared as the result of instillation of streptomycin and amithiozone. Most of the patients with colliquative tuberculosis of the skin had changes in the area of the thoracic wall with residues of a pleurisy that had occurred years or even decades earlier. The main manifestations consisted of nodes in the soft tissues, which partly had softened, and frequently of systems of fistulas, which undermined the thoracic wall. The fistulas were explored with a catheter and irrigated with a 1% solution of Substance VI for about 15 minutes. Within one week the penetrating odor subsided and the amount of secretion diminished. Irrigation of the fistular system every second day for several weeks proved satisfactory. Although good results were obtained with Substance VI alone, closure of the fistulas was obtained in a surprisingly short time by combined treatment with instillation of small depots of streptomycin in the wall of the fistular canal. Management of perforated or nearly perforated nodules consisted of excision of necrotic skin and of instillation of 0.3 gm. of Substance VI powder into the resulting crater.

Is Amebiasis a Controllable Disease? O. J. Blende. Northwest Med. 54:609-618 (June) 1955 [Seattle, Wash.].

The so-called chronic cyst passer may exhibit few or no significant symptoms, or his infection may be characterized by intermittent episodes of constipation or diarrhea. In others, the diarrhea may be relatively severe and the stools contain varying amounts of blood and mucus. Acute amebic dysentery is not infrequent in the tropics but is less common in temperate zones. Any of the clinical types of this infection may be followed by amebic hepatitis, acute or chronic amebic abscess of the liver, and less frequently abscesses in other organs. Outbreaks in Chicago and one in England demonstrated that amebiasis is a controllable disease. The only true source of infection is man. The possible modes of transmission are chiefly uncooked vegetables, contaminated water supplies, and the human carrier. All of these can be controlled. Observations on endemics in mental institutions demonstrated the necessity of personal hygiene and the danger of direct infection by fecal contamination. After mass treatment of 341 patients, only two needed additional treatment to obtain negative stools. Greater zeal is necessary in the protection of water supplies, particularly in the distribution system, since in one outbreak back siphonage from toilets, drainage from a defective sewer over the unclosed water cooler, and direct cross connections between sewer lines and water supply were found.

Anaemia in Systemic Diseases. M. C. Verloop. Acta med. scandinav. 151:367-380 (No. 5) 1955 (In English) [Stockholm, Sweden].

The causes of anemia were investigated in 43 patients, including 15 with chronic lymphocytic leukemia, 7 with chronic granulocytic leukemia, 4 with chronic erythremia or erythroleukemia, 4 with myelosclerosis and myeloid metaplasia, 11 with Hodgkin's disease, and 2 with subacute malignant reticulosis. A large percentage of patients showed pathological hemolysis; the most accurate methods of demonstrating this hemolysis were quantitative determination of fecal urobilinogen and determination of the survival time of transfused erythrocytes. The number of patients with a symptomatic hemolytic anemia in whom abnormal autoantibodies could be found was strikingly low. The abnormal erythropoiesis of these patients is not necessarily the only cause of their hemolysis. Normal transfused red blood cells also frequently disappear far too rapidly from the circulation. It must be assumed that abnormal activity of the spleen is an important factor in this mechanism, even without abnormal antibodies in the blood. The pathological hemolysis appears to be due, then, to the formation of erythrocytes with a reduced survival time and removal by the pathologically altered spleen of both homologous and transfused red blood cells. It is advisable to examine all patients with systemic diseases and anemia for abnormal hemolysis. The author believes that this hemolysis is extremely common in erythremia or erythroleukemia and in myelosclerosis with extramedullary hemopoiesis. Hemolytic anemia occurs far more frequently in lymphocytic leukemia than in granulocytic leukemia. Corticotropin and cortisone can cause striking improvement in the abnormal hemolysis not only in patients in whom abnormal autoantibodies have been demonstrated, but also occasionally in the absence of these antibodies. Splenectomy should be reserved for those few patients with a critical hemolytic anemia who respond not at all or insufficiently to hormone therapy. This study concerns cases of chronic leukemias only, but it has been recently shown by Schapira and co-workers that the anemia in patients with acute leukemia may often be the result of an abnormal hemolysis.

SURGERY

Ventricular Septal Defect: Clinical and Hemodynamic Patterns. S. G. Blount Jr., H. Mueller and M. C. McCord. Am. J. Med. 18:871-882 (June) 1955 [New York].

At the cardiovascular laboratory in Denver the diagnosis of isolated ventricular septal defect was made on clinical grounds in 63 of 580 patients with congenital cardiovascular disease. Cardiac catheterization was performed in 32 of these. The resulting physiological data confirmed the clinical impression in 21 patients. Evidence of an isolated ventricular septal defect was afforded by cardiac catheterization in two patients, in whom a diagnosis of pulmonary hypertension of unknown origin had been made. Twenty-three patients, therefore, presented conclusive evidence of an isolated ventricular septal defect and represent the basis for the present report. The patients ranged in age from 2 to 36 years. Analysis of the physiological data lead to the conclusion that the size of the ventricular defect was the sole factor determining the clinical findings. The physiological findings noted in four patients were compatible with the congenital anomaly that has been designated Eisenmenger's complex, namely, the presence of a systolic pressure in the right ventricle and pulmonary artery equal to or exceeding that in the systemic circuit, thereby resulting in a right-to-left shunting of blood. The authors think of the Eisenmenger complex not as an anatomic entity but as a stage in the natural history of the ventricular septal defect. Evaluation of the hemodynamic data of four other patients further supported this concept. These patients had marked pulmonary hypertension, closely approximating the systemic pressure, with extremely high pulmonary vascular resistances. The hemodynamic pattern of this group of patients differed from that in the first group of patients only by the absence of a definite right-to-left shunt at the time of catheterization, but cyanotic episodes with exertion were reported in three of these latter patients indicating intermittent right-to-left shunts. Thus the physiological changes in these two groups of patients differed only in degree. A distinctly different hemodynamic pattern characterized by moderate pulmonary hypertension and greatly increased pulmonary artery blood flow was noted in a third group. These patients had relatively large ventricular septal defects but had not developed changes decreasing the cross sectional area of the pulmonary vascular bed. Such changes may occur as the disease progresses, the patient ultimately presenting a clinical and physiological picture similar to that of the first two groups. A fourth group of patients showed little derangement from the normal hemodynamic pattern. The left-to-right shunt was of small magnitude. The authors believe that no surgical measures are indicated in patients with small ventricular septal defects in whom there is no significant pulmonary hypertension and left-to-right shunts are of small magnitude. Patients with large defects presenting severe pulmonary hypertension, marked increase in pulmonary vascular resistance, and left-to-right or right-to-left shunts of small volume probably have passed the stage where closure of the ventricular defect would produce significant beneficial results. The ideal candidates for closure of ventricular septal defects are therefore patients presenting mild to moderate pulmonary hypertension, slight to moderate increase in pulmonary vascular resistance, and left-to-right blood flow of high magnitude.

Experiences in the Course of Resection Therapy for Pulmonary Tuberculosis. H. H. Fiedler. Ztschr. Tuberk. **106**:77-83 (No. 2) 1955 (In German) [Leipzig, Germany].

On the basis of several case histories the author presents some experiences with the resection therapy of pulmonary tuberculosis. He warns against postponing resection too long in cases of unsuccessful collapse therapy. In one patient whose history is presented a lung had been practically destroyed by a number of cavities, despite various forms of collapse therapy and treatment with streptomycin and *p*-aminosalicylic acid. Although the patient showed signs of amyloidosis and her condition seemed rather hopeless, lobectomy was carried out. She died a week after operation, and autopsy revealed general intoxication and severe amyloidosis, particularly of both kidneys. Such general organic changes negate the result of a successful resection. Internal fistulas with residual empyema cavities are a definite indication for pulmonary resection. One of the case histories shows that previous ineffective thoracoplasty does not contraindicate a subsequent resection. On the contrary such patients tolerate resection well. Sanatorium therapy may prove helpful for patients who have undergone pulmonary resection.

Surgical Approach to the Vertebral Bodies in the Midlumbar Region for the Treatment of Limited Forms of Pott's Disease in the Adult. J. Debeyre, S. De Sèze and C. Moreau. Semaine hôp. Paris **31**:1729-1735 (May 20) 1955 (In French) [Paris, France].

The effective protection afforded by antibiotics has made it possible for the authors to operate on 35 patients with tuberculous osteitis without a single case of miliary dissemination or tuberculous meningitis. The lesions in the 11 patients reported on consisted of limited foci localized in the second, third, and fourth lumbar vertebral bodies. Most of the patients were young adults with recent lesions and backache of only a few months' duration. Their general condition was satisfactory and in none was the presence of an abscess detectable on clinical examination. The discovertebral involvement shown by the roentgenograms was not extensive, consisting merely of discreet compression of the disk and either a superficial erosion of the surface adjacent to the disk or of single or multiple geodes in the vertebral body. Other tuberculous foci, either elsewhere in the spine or in the viscera, were looked for but not found. Preoperative treatment consisted of absolute immobilization in a plaster cast and chemotherapy with streptomycin, *p*-aminosalicylic acid, and isoniazid for a period of one to three months. One month of preoperative treatment was considered adequate in most patients, because of the limited character of the foci and because administration of the antituberculous medications for a longer period might have led to the appearance of drug resistance. The lesions are often unilateral, leaving no doubt about the side from which they should be approached, but there are times when the choice of an approach is less easy because, whichever side is used, the removal of the focus may be inadequate, leading to fistulization. An operation in two stages, first from the right and then from the left, was made necessary in one patient by this complication. Exposure is obtained through a lumbar sympathectomy incision, the site of the lesion is identified, and the psoas muscle is explored. Intrapsoic abscesses, when found, should be opened and their contents evacuated. The affected disk and vertebral body are then curetted and the tuberculous focus completely removed. The procedure is well tolerated, and after the third month the patients can be allowed to be up, beginning with one hour a day. Six months after the operation, those who wish to do so can work half time. Full-time work can be resumed at the end of a year. All the patients, some of whom have been observed from one and a half to two years, seem to be cured, but the tendency of tuberculosis to become reactivated makes it advisable to withhold final judgment until a later time.

The Surgical Management of Funnel Chest. P. F. Hausmann. J. Thoracic Surg. **29**:636-648 (June) 1955 [St. Louis].

The author reports observations on 51 patients with funnel chest who were operated on, and on 10 patients in whom surgical treatment was deemed unnecessary. Five of the 51 operated on were under six months of age, 10 were over 5 years, and 36 ranged in age between 6 months and 4 years. The author believes that between 12 and 24 months is the ideal age for surgical treatment. There were no surgical deaths, and only one minor wound infection occurred. The simple ligament-cutting operation was performed in only two instances, both in children not over 4 months of age. The extensive subperichondrial resection of costal cartilages was done in the other 49 patients. The number of cartilages removed depended on the number involved in the deformity and varied from segments of three to six or seven cartilages bilaterally. The author was careful to remove all of the involved portion of each cartilage, because this eliminates the need for second operations for recurrent deformity. Subperichondrial resection is advisable because regeneration of cartilage or bone occurs rapidly, and adequate stability of the chest wall is assured in less than two weeks, and because by judiciously placing sutures in the perichondrium of resected ribs the shape of the chest wall can be altered within limits so that external fixation of the sternum is scarcely necessary to ensure regeneration of cartilage in the corrected position. In other words, the shape given to the anterior chest wall by carefully placed sutures in the perichondrium was made permanent by cartilaginous regeneration. Postoperative physical therapy in the form of breathing exercises, posture training, and shoulder exercise is another important factor in preventing the recurrence of funnel chest. Significant hypertrophy of the substernal ligament was noted in only 13 patients, and thickening of sufficient magnitude to cause abnormal traction on the lower sternum was observed in only five. It is difficult, therefore, to attribute the deformity to the pull of this ligament on the sternum. The deformity is primarily skeletal, due to an overgrowth of cartilage rather than to abnormal stresses on the skeleton by hypertrophied ligaments and diaphragmatic muscles.

Unusual Manifestations of Hyperparathyroidism. L. Goldman. Surg., Gynec. & Obst. **100**:675-689 (June) 1955 [Chicago].

The histories of seven patients show that, in spite of unusual manifestations of hyperparathyroidism, the chemical findings are a common denominator. Hypercalcemia is the most important of these chemical changes and requires accurate determinations of the serum calcium level. The incidence of hyperparathyroidism as a cause of renal calculi is sufficient to warrant chemical studies in every patient with nephrolithiasis. Local bone cysts, so-called giant cell tumors—particularly of the mandible—or generalized skeletal demineralization may be the presenting symptom. The presence of any of these signs is an indication for chemical and further roentgenologic studies. Nausea, vomiting, and dehydration may simulate acute gastrointestinal disturbances. The bone lesions heal following removal of the tumor or tumors, but the renal lesion is often progressive. Renal insufficiency and hypertension are common sequelae. Complete exploration of the thyroid area, the retrotracheal and retroesophageal areas, the anterior and posterior mediastinum, and the thyroid gland should be carried out in every patient before removal of any tissue. Attempts should be made to visualize all normal parathyroid glands. Signs of postoperative tetany occurred in every one of these patients when all hyperfunctioning tissue was removed. This sign is a welcome indication of complete ablation of all excess parathyroid tissue and should, therefore, be sought and confirmed before antitetanic therapy is started.

Gastric Carcinoma and Sarcoma. W. Walters. Postgrad. Med. 17:472-478 (June) 1955 [Minneapolis].

The author shows that improvements in the treatment of malignant lesions of the stomach have increased the five year survival rate by more than 180% in about 10 years. This increase has been due not only to the increase in the percentage of patients whose lesions have been removed by more extensive resection but also to a better understanding of how to prepare patients for operation by use of antibiotics when necessary, by better anesthesia, and by a better program of postoperative care based on the physiological requirements of each patient. Unfortunately 20 of each 100 patients with malignant gastric lesions coming to the Mayo Clinic from 1940 to 1950 were judged to have inoperable lesions on physical examination, and an additional 36 had lesions that were found at laparotomy to be inoperable. This means that 56 of each 100 patients lost any chance for a five year survival. A review of thousands of cases of cancer of the stomach observed at the Mayo Clinic disclosed that common causes of delay in recognizing the lesions were: (1) an erroneous diagnosis of benign peptic ulcer, with treatment for ulcer without x-ray examinations of the stomach and duodenum; (2) relief of symptoms by a medical regimen for ulcer leading to the erroneous clinical interpretation that the ulcer was benign; and (3) prolonged medical treatment of roentgenologically diagnosed "ulcers of the stomach" without repeated roentgenographic and gastroscopic examinations. Eighty per cent of patients operated on at the Mayo Clinic for gastric carcinoma who had histories typical of ulcer were relieved of symptoms, sometimes for months and sometimes for years, by a medical ulcer regimen. Other common causes of delay are: failure to recognize the significance of achlorhydria on gastric analysis and the value of gastric analyses in all middle-aged patients with dyspepsia; failure to recognize the value of abdominal exploration in patients with persistent dyspepsia or epigastric discomfort, especially when there has been loss of weight with and without anemia; failure to recognize that large gastric tumors may not be palpable because of their high location in the stomach (under the costal margin); and failure to persist in a clinical diagnosis and insist on abdominal exploration when x-ray examinations of stomach and duodenum have failed to demonstrate a lesion. Another common cause of delay in identifying the true character of the lesion is due to failure to advise removal of gastric polyps that may be malignant. Sarcoma of the stomach usually cannot be distinguished from carcinoma prior to operation. The sarcomas are usually lymphosarcomas, and they occur in the stomach in the proportion of about 5 to 100 carcinomas. The author advises resection with surgical removal of the lesion if possible, and if the lesion is a lymphosarcoma, x-ray therapy should be given when healing of the anastomosis is complete. Earlier recognition of the presence of a gastric malignancy is in the hands of the family physician and the internist.

Rupture of the Spleen. J. L. Connell. M. J. Australia 1:676-683 (May 7) 1955 [Sydney, Australia].

This report is concerned with rupture of the normal spleen, which is the most commonly damaged organ of the abdomen. The frequency of its rupture is due to its friable nature, the fact that it lies suspended by the lienorenal and gastrosplenic ligaments and is quite mobile, and the fact that the convex surface of the spleen is closely applied to the thoracic cage and any damage to the overlying ribs may rupture it. Rupture of the spleen may be present clinically in three forms. The most frequent form is primary rupture, in which splenic hemorrhage is immediate and continuous. These patients usually display obvious signs of internal hemorrhage. The second form is characterized by delayed clinical manifestations. Patients belonging to this group have a history of injury that usually produces shock. The patient recovers from this, apart from soreness over the lower left ribs. This group falls into two subdivisions: (1) symptoms and signs of shock and intra-abdominal injury return in a few hours, either slowly or very suddenly, and (2) the patient remains more or less asymptomatic for days, weeks or months, and then suddenly there is secondary bleeding from the damaged spleen, producing symptoms and signs. The last group comprises those patients in whom the splenic bleeding does not give rise to sufficient signs to merit laparotomy. In other words, they have a minor rupture of the spleen in which the diagnosis is not made and the laceration heals spontaneously. A ruptured spleen may produce a great variety of clinical symptoms and signs. There is nearly always a history of injury; this is most often a blow over the lower ribs on the left side, and frequently fractured ribs are present. However, the force may be applied anywhere to the abdomen, or it may be due to a fall from a height. Pain is invariably present and may vary from a dull ache to a most excruciating agony. Kehr's sign, which consists of pain in the left shoulder tip, is referred pain, due to irritation of the central part of the diaphragm. It is present in only about 25% of cases, and it has been given undue significance in the past. If the sign is absent it may often be produced by tipping the patient into the Trendelenburg position for a few minutes. Patients with pain in the shoulder or neck often state that the pain comes on only when they are in the supine position or is greatly accentuated by it. Frequently deep breathing will precipitate or enhance the pain. Some patients complain of discomfort in the rectum and tenesmus. This is due to blood in the pelvis, and peritoneal tenderness on rectal examination is often present and should be looked for. Pallor is almost constantly present and arouses suspicion of the diagnosis. There is abdominal tenderness and frequently distention. Increased dulness in the splenic area and in the left flank is of great significance. Roentgenologic signs of ruptured spleen are the following: increased density in the left hypochondrium, elevation of the left leaf of the diaphragm, displacement of the stomach to the right, and the presence of free fluid between loops of intestine. Abdominal paracentesis may prove helpful. Ruptured spleen is sometimes misdiagnosed, symptoms being wrongly attributed to fractured ribs or bruised muscles alone, ruptured intestine, ruptured liver, lacerated kidney alone, perforated ulcer, or ruptured ectopic gestation.

Present Rules of Surgical Treatment of Secondary Abdominal Echinococcosis: Based on One Hundred Ten Cases. B. Kourias. Lyon chir. 50:407-417 (May-June) 1955 (In French) [Paris, France].

Among 1,745 hydatid cysts operated on between 1914 and 1953 in Athens, Greece, 110 cases of secondary abdominal echinococcosis were found (6.3%). There has been some decrease in this form of hydatidosis in recent years. In 60% the primary cyst was located in the liver, in 6% in the spleen, and in 8% in both these organs; 35.4% were located in many organs, in 27% the dissemination was limited, and in 16% the cysts had invaded the pelvis and the genital organs. There were also some rare forms of the disease: hydatid choleperitoneum, hydatid ascites, hydatidosis with hernia, free cysts of the peritoneum, and pseudotuberculosis of hydatid origin, among others. The mortality rate was 8.1%. No deaths occurred after 1948 because of the reduced number of infected and ruptured cases. Modern surgical techniques used in the treatment of this disease include total or partial cystectomy, ablation of the parasitic cysts with primary suture with or without packing, marsupialization, minimal drainage, extensive resection, and the use of the thoracoabdominal route. Many patients who in the past would have needed two or more operations can now be cured by operation in one or two stages. Treatment of secondary abdominal echinococcosis by biological methods shows some promise but does not constitute definitive therapy for the basic disease. Since the improvement it brings is only temporary, the author concludes that the only rational treatment is operation.

Obstruction of the Small Intestine by Swallowed Foreign Bodies. J. Francillon and J. Moisant. Lyon chir. 50:418-425 (May-June) 1955 (In French) [Paris, France].

The treatment of ileal and jejunal obstruction caused by a swallowed foreign body depends on whether the obstructing agent is an inorganic object, something ingested as food, or material used for therapeutic purposes (usually synthetic mucilage taken in an effort to combat constipation). The clinical findings and prognosis for true (inorganic) foreign bodies are worse than for the other types. Good results of treatment depend mainly on early diagnosis, which allows enough time for an unhurried decision and the use of the simplest, most direct methods. In certain patients prompt operation is needed because of severe symptoms of obstruction, but, as a general rule, surgical treatment should be conservative. The decision whether or not to operate should be made according to case. If on laparotomy transparietal propulsion is inadequate or dangerous, enterotomy should be performed, where possible, in healthy tissue. Enterectomy is reserved for those lesions of the intestinal wall that are definitely or probably irreversible. Exteriorization and shunting are only palliative measures and are of little value.

Comminuted Fractures of the Patella. H. R. Schönbauer. Arch. orthop. u. Unfall-Chir. 47:266-271 (No. 2) 1955 (In German) [Munich, Germany].

From a series of 574 patients with 578 patellar fractures the author selected 32 of the most severe (crushed or comminuted) fractures for study. The therapeutic results were analyzed with regard to the preservation or removal of the patella. After extirpation of the patella the functional result was better, and no arthrosis of the knee-joint developed. The duration of treatment was neither shortened nor prolonged by extirpation. Although there was a greater reduction in the capacity to extend the knee-joint, and the extensor muscles of the thigh showed more severe atrophy after patellar extirpation, the resulting subjective symptoms were slight. None of the patients in whom the crushed patella was removed were obliged to change their occupation, nor did they become unable to participate in sports, whereas this did happen in those in whom the patella was preserved. The restoration of the extensor apparatus of the knee-joint depends on the restoration of the gliding surface of the patella with simultaneous suture of the torn reserve extensor apparatus. If the patellar gliding surface cannot be restored, it is best to remove the entire patella.

Evaluation of Results of Digital Flexor Tendon Grafts. J. H. Boyes. Am. J. Surg. 89:1116-1119 (June) 1955 [New York].

The result of a surgical procedure can be evaluated in the same way as the result of any manual art if three fundamentals —materials, principles, and technique—are considered and if the result can be measured and recorded in a single unequivocal figure. The author devised such a standard of judgment for digital flexor tendon grafts. The result can be expressed in a single figure and accounts for variations in the three factors mentioned. Results of flexor tendon grafting in the digits are best when tissues are least damaged, when a full-length graft is used, and when exacting technique is followed. Under these conditions it has been shown that 25% of all graftings will result in flexion of the pulp of the finger to reach the distal crease of the palm; in 50% flexion will occur to within one-fourth of an inch; and all will flex to within ¾ in. of the distal crease of the palm.

Treatment of Postoperative Vomiting. P. S. Marcus and J. C. Sheehan. Anesthesiology 16:423-427 (May) 1955 [Philadelphia].

Marezine (a brand of cyclizine lactate) had been investigated by others in the oral form. This report is concerned with the injectable form. It has an atropine-like and an antihistamine-like action. In a preliminary study the incidence of postoperative vomiting was ascertained in 1,000 consecutive patients and was found to be 21.3%. Of 100 consecutive patients anesthetized with some type of general anesthetic who had not received Marezine, 19 had postoperative vomiting, and in 100 consecutive patients who received spinal anesthesia the incidence of vomiting was 18%. This makes the combined incidence 18.5%, which is within range of a general incidence of 21.3%. Marezine was given both prophylactically and therapeutically to 322 patients. If it is given in doses of 50 mg. for adults and 25 mg. for children and is administered in the deep subcutaneous tissue one-half hour before the contemplated end of the surgical procedure, the postoperative vomiting will be decreased. In this series the incidence was reduced from 18.5% to 10%. Marezine seemed to be of value in arresting further vomiting during the immediate postoperative period. The authors believe that this should be investigated more fully in an attempt to evaluate the usefulness of the drug if continued through the first 24 to 36 hours of the postoperative period. In this series it produced no local reaction and no untoward effects.

NEUROLOGY & PSYCHIATRY

Evaluation of Nerve Lesions After Intramuscular Injections. W. Fuhrmann and G. Gruenwaldt. Chirurg 26:210-216 (May) 1955 (In German) [Berlin, Germany].

The authors had to give expert testimony in seven cases in which lesions of the sciatic nerve resulted from intragluteal injections. There were three children among the five patients in whom a lesion of the sciatic nerve resulted from injections of sulfonamide preparations. In this connection the authors mention six other children in whom lesions resulting from injections caused paralytic clubfoot deformities. These experiences indicate that particularly in children great caution is necessary when intramuscular injections are given, the more so since the prognosis as regards recovery is rather poor. After four months to six years only 2 of 13 patients showed even slight improvement of the nerve lesion. The authors showed that an atypical course of the sciatic nerve cannot explain the nerve damage after an intragluteal injection; a local nerve lesion can be differentiated from toxic polyneuritis; and lesions resulting from strangulation by scar tissue and secondary degeneration of the nerve have been observed but are extremely rare. These can be assumed as the cause only if there have been no pains during and for several days after the injection and if the paralytic symptoms developed slowly. Experimental studies indicated that sulfonamide preparations as well as irgapyrine, which contains equal parts of phenylbutazone and aminopyrine, may cause nerve lesions, provided they reach the nerve. There is, however, no proof that with careful injection technique the drug will penetrate to the nerve. The assumption that the drug may be dispersed in the musculature and may advance to the nerve can be made only if there is no pain during the injection and the paralysis develops slowly over several hours or days after the injection. If there is pain during the injection or immediately after it, a defective injection technique must be assumed. All experiments were made with concentrated drugs. The fact that damage from injections is relatively rare might be interpreted as proof of the fact that even in patients in whom the drug is widely distributed within the tissues only slight quantities would reach the nerve, and if so, in an extremely diluted state. Such slight concentrations would not cause paralysis. Thus, using a correct technique will probably prevent injurious effects. The intragluteal injection should be made at least two fingerbreadths below the crest of the ilium, and the point of the needle should be directed toward the crest of the ilium, and the injection should be made slowly. This method was used in over 6,000 injections of irgapyrine, and there was not a single case of nerve injury.

Neurosurgery of the Ansa Lenticularis in Dyskinesia and Parkinson's Disease: Principles and Techniques of a Personal Intervention. F. Fénélon. Semaine hôp. Paris 31:1835-1837 (May 26) 1955 (In French) [Paris, France].

The author has treated 61 patients with dyskinesia by electrocoagulation of the ansa lenticularis: one with choreoathetosis and 60 with paralysis agitans. His method uses the transfrontal route as the least harmful. Physiologically, the procedure appear rational because it treats extrapyramidal disease in the extrapyramidal tract, intervening immediately below the primary lesion. The operative mortality in the series was two, both patients being extremely poor risks. Results were good in 70% of the remaining patients, followed for from six months to four years.

Hereditary Tremor. B. V. Jager and T. King. A. M. A. Arch. Int. Med. 95:788-793 (June) 1955 [Chicago].

In a single family with hereditary tremor, 24 members, extending over four generations, were examined for this trait. Neurological examination showed wide variation with regard to severity of tremor, even in siblings of about the same age. A tremor of the upper extremities was observed in 19 of the 24 persons, but on the basis of questioning numerous members of the family only 4 of the 24 were thought to have this difficulty; two others were presumed to have "shaking palsy." Most of the affected persons were aware that emotional factors aggravated the tremors and that alcohol afforded some relief. The diagnosis of hereditary tremor may not always be easy. The familial history in conjunction with the presence of static and intention tremor and in the absence of other neurological changes usually permits a diagnosis. Difficulty arises in that one occasionally sees similarly distributed tremors in the absence of a familial history. In such cases it would be advisable to examine many other members of the family, since milder forms of tremor frequently go unrecognized. Basically, the symptomatology of hereditary tremor is that of a neocerebellar-like disorder. Many familial and nonfamilial diseases exist in which cerebellar symptoms are prominent, but disorders of gait and other neurological abnormalities of a noncerebellar type may also be present in such patients. In hereditary tremor, the gait and equilibrium are unimpaired. In the family studied, the pattern of inheritance of the disorder appears to be that of a simple somatic dominant. Treatment of hereditary tremor is unsatisfactory. Differential diagnosis from paralysis agitans and reassurance as to the benign character of the disorder are important.

Treatment of Multiple Sclerosis with Low-Fat Diet: Results of Five and One-Half Years' Experience. R. L. Swank. A. M. A. Arch. Neurol. & Psychiat. 73:631-644 (June) 1955 [Chicago].

A low-fat diet was used in 264 patients with multiple sclerosis. Continuous contact was maintained with 210 of the 264 patients, and 158 of these have remained on the low-fat diet. The present report deals mainly with the first 47 patients to be placed on the diet who remained on diet and who have been followed closely for four to six years. The following foods were forbidden: whole milk, butter, cream, cocoa, chocolate, and all foods containing these substances. The diet permitted 15 gm. of hard fats (animal fats, margarine, lard, and shortening) and 15 gm. of vegetable oil or a substitute per day. In so far as possible, the intake of fat should be evenly distributed throughout the day. All patients should consume at least one egg and 5 cc. of cod liver oil daily. Fats or oils used for cooking or baking must be included when determining the daily fat intake. Substitutes for these amounts of fats in the form of fowl, lamb, beef, liver, and so on are listed, as are also the permitted foods. This diet seemed to lessen the severity of the disease by reducing the frequency and severity of the exacerbations. Its usefulness is greatest early in the disease, before significant disability and a steady progression of symptoms have developed. The period of observation has now been sufficiently long to give the author some confidence in his observations. Serious consideration is given to the hypothesis that patients with multiple sclerosis have a basic defect in the suspension stability of their blood, which is upset by the hyperlipemia following heavy fat meals.

On the Prognosis of Brachialgia. A. Bergsman, G. von Reis and F. Sahlgren. Acta med. scandinav. 151:391-398 (No. 5) 1955 (In English) [Stockholm, Sweden].

A follow-up study lasting up to eight years was made of 100 patients with brachialgia. Forty-eight patients were classed as group 1 because they had symptoms suggestive of a nerve root lesion (radicular distribution of pain, intensification of pain on coughing and sneezing, precipitation of the pain by the neck-compression test with radiation into the arm, sensory disorders, reflex disturbances, and pareses). Group 2 consisted of 38 patients in whom the presence of a cervical disk lesion was highly probable but in whom the diagnosis could not be confirmed by the symptoms mentioned above; the psychoneurotic element in them was not considered important. The remaining 14 patients were classed as group 3 because the neurotic factor played a large part in their disease. A further division of the patients into those with an observation period of less than four years and those with more than four years' observation showed that of 56 patients in the first category 27 and of 44 in the second category 19 obtained complete relief. Thus, patients with brachialgia usually regain a certain amount of working capacity fairly soon, although in many instances full restoration may take a long time. The prognosis is good, even in patients with a high degree of disability. A psychoneurotic component is a bad prognostic sign, however, as shown by the fact that only one of the 14 patients in group 3 regained full working capacity during the period of observation. Symptoms suggestive of nerve-root lesion show a definite tendency to disappear as early as two years after onset. Only rarely do they last as long as eight years.

GYNECOLOGY & OBSTETRICS

Pregnancy After Vaginal Operation. M. Olki and O. Kinnunen. Acta obst. et gynec. scandinav. 34:30-40 (No. 1) 1955 (In German) [Stockholm, Sweden].

A questionnaire concerning postoperative pregnancy was sent to 363 women less than 40 years old who had undergone vaginal operations. Of the 202 women who answered the questionnaire, 57 had operations involving vagina and cervix (group 1), 14 operations for fistulas (group 2), 36 operations for incontinence (group 3), 15 minor vaginal operations (group 4), 43 major vaginal operations (group 5), 32 minor cervical operations (group 6), and 5 major cervical operations (group 7). Seventy-five (37%) of the 202 patients became pregnant after the operation, 16 in group 1, 6 in group 2, 8 in group 3, 8 in group 4, 16 in group 5, 18 in group 6, and 3 in group 7. Thus the postoperative incidence of pregnancy varied from 28% to 60% depending on the type of operation performed. Postoperative dyspareunia was rarely complained of, but in each of the seven groups most of the women practiced contraception. In 65 of the 75 pregnant women, the pregnancy continued to term. Delivery was normal in 52, 11 underwent cesarean section, and in 2 forceps delivery was necessary. In 5 (7.7%) of the 65 patients the vaginal operation was the direct indication for cesarean section. The authors' observations showed that a vaginal operation performed on a woman of reproductive age does not have any untoward effect on either sexual intercourse or a subsequent pregnancy.

Latent Genital Tuberculosis in Women. I. Halbrecht. Rev. méd. Cordoba 43:89-94 (March) 1955 (In Spanish) [Cordoba, Argentina].

A series of 2,500 sterile women was observed for five years. Of these, 160 had latent genital tuberculosis as verified by: (1) cultures of menstrual secretion, (2) endometrial biopsy or endometrial curettage, or (3) histological examination of the oviducts, surgically removed for tubal occlusion. Sterility was primary in all patients but three who had one or more than one child before becoming sterile. Early signs observed in these patients indicated that sterility caused by genital tuberculosis is due to unilateral or bilateral partial or total occlusion of the oviducts or to rigidity of the tubes from scar formation or inflammation. Genital tuberculosis as a cause of sterility should be searched for in all patients who suffer from extragenital tuberculosis or have a history of extragenital tuberculosis and pleurisy. The extragenital tuberculosis is latent and follows a slow course, but it may remain potentially active for a long time after cicatricial regression or complete cure of the original primary focus of tuberculosis. Genital tuberculosis in women as a cause of sterility calls for treatment, preferably with streptomycin and *p*-aminosalicylic acid. This treatment was given to 75 patients who were observed for two to five years. Sixty were cured and eliminated no more tubercle bacilli in the urine. Three of the patients who had antibiotic treatment for latent genital tuberculosis restricted to the oviducts became pregnant after treatment and had normal full-term babies. Forty patients had antibiotic treatment when the endometrium was already involved. Only one became pregnant and had an abortion in the third month of pregnancy. None of the patients in this group received intrauterine application of radium. The author, however, has observed unfavorable results in six patients. Recurrence of genital tuberculosis after intrauterine application of radium was frequent and radium caused complete atrophy of the endometrium in two of six patients treated.

PEDIATRICS

Effect of Triethylene Thiophosphoramide in the Treatment of Leukemia and Certain Lymphomas in Infants and Children. N. J. Smith, S. Rosello and H. Shay. *J. Pediat. 46:493-505 (May) 1955 [St. Louis].*

Many ethylenimine derivatives were investigated for their effects against experimental leukemia in rats. N, N', N'', triethylene thiophosphoramide (thio-TEPA) was among the most effective, and so it was used in a large number of patients with leukemia, lymphomas, and inoperable malignant growths of various types. The experience with this drug in children is reviewed. Twenty-one patients under the age of 15 years were treated with thio-TEPA in a 12-month period. There were 12 children with acute leukemia, 3 with differentiated types of myelocytic leukemia, 5 with lymphosarcoma, and one with Hodgkin's disease. This agent seems to be of use in the temporary control of lymphosarcoma and chronic forms of leukemia. It is contraindicated in the therapy of acute leukemias of childhood. The toxic manifestations from overdosage of the agent have been limited to bone marrow depression. If this complication is to be avoided therapy must be guided by careful clinical and laboratory evaluation of the patients during the course of treatment. Thio-TEPA appears to have the advantage of a wider margin of safety between the toxic and therapeutic doses than do other ethylenimine derivatives currently available.

Influence of Type of Feeding on pH of Stool, pH of Skin, and Incidence of Perianal Dermatitis in the Newborn Infant. A. G. Pratt and W. T. Read Jr. J. Pediat. 46:539-543 (May) 1955 [St. Louis].

Perianal dermatitis is frequently seen in hospital nurseries. The severe form is characterized by multiple, small, superficial ulcerations, while mild disease may often be missed unless the buttocks are manually separated. Perianal dermatitis is not to be confused with diaper rash, which occurs later and affects the convex surfaces of the thighs and buttocks and the pubic region. Perianal dermatitis has been shown to be more frequent among the artificially fed infants than in the breast-fed infants. The substitution of lactose for vegetable carbohydrate in the formula has lowered the incidence significantly. It has been postulated that this difference may be due to a variation in stool pH. To determine the effect of various feedings on pH of the stool and of the skin, and on the relation of pH of the stool to incidence of perianal dermatitis, examinations were made on 251 newborn infants, of whom 140 were breast-fed, 50 were fed a prepared formula approximating human milk, and 61 were fed an evaporated cow's milk and maltose-dextrin formula. During the first three days of life there was little difference in mean pH observations regardless of feeding. From the fourth day, pH of the stool and of the perianal skin became increasingly acid for the breast-fed infants and for those fed simulated human milk, but remained relatively unchanged for those fed the cow's milk formula. The axillary skin pH became more acid with age regardless of feeding. The incidence of perianal dermatitis varied with the pH of the stool and of the perianal skin, being less frequent the more acid the stool and perianal skin. These findings support the belief that the stool pH of infants is directly affected by the type of feeding. The perianal skin with which the stool comes into contact is correspondingly changed. If the pH of the stool is such that the perianal skin pH is raised above the range found in breast-fed infants, the incidence of perianal dermatitis is increased.

Pneumonia Complicating Oral Thrush Treated with Mycostatin, a New Antifungal Antibiotic. A. J. Beckmann and J. E. Navarro. J. Pediat. 46:587-591 (May) 1955 [St. Louis].

Thrush caused by Candida (Monilia) albicans is a common oral infection in newborn infants, its incidence being as high as 20% in some newborn-infant nurseries. Some investigators established that oral thrush developed in each instance in which C. albicans was found in the mouth of a newborn infant but in no instance when only other forms of yeast were present, and that the average interval after birth for the development of clinical thrush was 8.2 days. There seems to be a relationship between maternal vaginal moniliasis and oral thrush, but infection may occur also by contact other than directly from the vagina. Pneumonia and esophagitis are possible complications of oral thrush in the newborn infant. In one infant the monilial infection was found on the 10th day of life and did not respond to topical medications. A few days later there was a deterioration of the general condition with symptoms of severe respiratory distress. The antibacterial drugs given at first did not relieve either the thrush or the respiratory distress. Mycostatin, a new antifungal agent, was given in the form of a flavored powder. One teaspoonful (175,000 units) was mixed with 1 oz. of milk and administered by spoon every six hours. Within 48 hours improvement of the oral lesions was evident. After the supply of Mycostatin powder was exhausted, tablets containing 500,000 units each were crushed, and one was given in milk four times a day. Coincident with this increase of dosage, looser, more frequent, and darker-colored stools were noted. After six days the flavored powder was again available and two teaspoonfuls were given every four hours. Stools gradually returned to normal without special treatment. Clinical and roentgenological improvement of the pulmonary condition was noted in two weeks. The infant was discharged one month after admission.

Pediatric Allergy. S. C. Dees. M. Ann. District of Columbia 24:225-232 (May) 1955 [Washington, D. C.].

In spite of the trend toward earlier diagnosis of an allergic basis for nasal symptoms, this cause for so-called colds is still not recognized in many children, perhaps because the symptoms are not seriously incapacitating. The diagnosis of allergic rhinitis is usually simple. The nasal mucosa has a pale boggy appearance; the turbinates are large and obstruct the nose; and the discharge is a clear, nonirritating mucus. Staining nasal discharge for eosinophils is a reliable laboratory test. Whereas eosinophils indicate an allergic rhinitis, polymorphonuclear neutrophils predominate in infectious rhinitis. After symptomatic treatment of allergic rhinitis, in which antihistamines may be helpful, efforts should be made to discover the cause and to treat it either by avoidance or desensitization. Infants and young children tolerate desensitizing injections as well as, or better than, older children and adults. Asthma, particularly the first attack, is frequently diagnosed by exclusion of other conditions. If the physician knows that the child has had feeding difficulties relieved by diet changes; frequent colds without much fever, controlled by antihistamines, and not contracted from others; a skin rash such as eczema or hives; and a family history of allergy, he may assume that the wheezing is asthma, no matter how young the patient. Eosinophilia in the nasal secretions and in the blood is likewise of diagnostic value. The mother should be asked to describe the first attack of wheezing, including where the child was and what he was doing. This may identify the causative allergen. If the first attack cannot be clearly recalled, or the trouble began insidiously, infection may be the cause. True asthma responds promptly to epinephrine and aminophylline. If such relief does not occur, either the disorder is not asthma, or it is accompanied by infection. Skin tests may give valuable corroborative evidence. The histories and chest roentgenograms of five children, who were believed to have asthma, show the difficulties involved in diagnosing asthma in young children. The final diagnosis in these cases was foreign bodies in the air passages, cystic fibrosis of the pancreas, and atelectasis or asthma. Acute respiratory distress due to almost all causes is improved by oxygen, removal of obstruction to the airway, and relief of the anxiety that accompanies anoxemia. Moderate sedation is helpful for the anxiety, but opiates have no place in the treatment of asthma. In desperately ill asthmatic patients intravenous administration of corticotropin or hydrocortisone is usually effective in three or four hours. Intramuscularly injected cortisone may not exert its full effect for 48 hours after it is given, and its effect will last that long after the last dose. Orally administered cortisone is effective for eight hours, and therefore doses should not be more than eight hours apart. Corticotropin and cortisone may produce hypertension, salt retention, and potassium deficiency; furthermore, they do not cure allergy. Antibiotics should be used with caution in allergic children, because they have a higher rate of sensitization to these drugs than do nonallergic persons. The physician should ascertain whether there is a real need for antibiotics, and he should inquire about any reaction to previous courses of the drug.

DERMATOLOGY

Silicon in Prophylaxis and Therapy of Industrial Dermatoses. H. Järnecke. Deutsche med. Wchnschr. **80**:755-756 (May 13) 1955 (In German) [Stuttgart, Germany].

Silicon-protective (Setaderm-protective) ointment consists of methylpolysilicon oil on a nonirritating wax base. This oil is intermediate between organic and inorganic compounds. Its basic structure consists of silicon atoms that are united by oxygen atoms, and, therefore, it has a chemical structure similar to that of sand and quartz. Various organic groups are bound to the silicon, and thus a highly stable molecular structure results. Because of this structure the methylpolysilicons are highly resistant, chemically indifferent, and stable on heating and cooling, and have a high surface activity. Combined with wax they form a film, which spreads as a protective layer on the skin and excludes dirt, water, and watery solutions. The effect of the pure silicon oil on the skin was tested in 52 persons, and none of them suffered any damage to the skin, although some showed a positive reaction to a simultaneously performed soap test, suggesting a general hypersensitivity of the skin. One hundred forty-eight workers with industrial dermatoses were then treated with the silicon-protective ointment. After the application of the ointment the eczematous lesions healed, and new irritations of the skin no longer occurred. Therapeutic failures were observed in only 5 of the 148 patients.

Hirsutism. K. R. Crispell, W. Parson, G. F. Hollifield and others. GP **11**:82-92 (May) 1955 [Kansas City, Mo.].

Patients with hirsutism may be placed in one of three categories: hirsutism with virilism, hirsutism with a nonvirilizing endocrine disorder, or hirsutism with no recognizable endocrine disorder. The reason for the condition can almost always be discovered, but unfortunately the hirsutism does not always disappear after correction of the underlying endocrinopathy. Most hirsutism is of the idiopathic variety for which the only treatment is manual removal of the hair. Although the nature of the basic disease in the authors' 12 patients ranged widely, hirsutism was usually the complaint that brought them to a physician. The second most common complaint was irregular menses. One of the patients had hirsutism with mild virilism that had been induced by the administration of androgen. The hirsutism did not completely disappear on discontinuation of this treatment. The authors warn against the irrational use of androgen therapy in any woman.

Premalignant Fibroepithelial Tumors of Pinkus and Basocellular Epithelioma: Based on Two New Cases. R. Degos and J. Hewitt. Ann. dermat. et syph. **82**:124-139 (March-April) 1955 (In French) [Paris, France].

Two new cases of fibroepithelial tumors bring the number reported to nine, when added to those originally described by Pinkus in 1953 and those identified by him in the literature. The tumors remain benign for long periods of time. They are often multiple. They are often confused with fibromas, seborrheic verrucae, or superficial epitheliomas. Their histology is characteristic, however; it shows an epithelial network that gives rise to basocellular buds and a fibromatous hyperplasia of the dermis. These tumors develop into basocellular epitheliomas and are to be considered a special variety of this lesion. One of the authors' patients had tumors from childhood; this would seem to support the concept of a nevoid, embryonic origin of basocellular epitheliomas, which is not in accordance with the ideas of Pinkus. Another previously unreported characteristic that may be present in fibroepithelial tumors is the presence of horny excrescences. This complicates the differential diagnosis from seborrheic verrucae.

UROLOGY

Considerations on Renal Tuberculosis. G. Aveta and G. Sesia. Minerva med. **46**:749-756 (March 21) 1955 (In Italian) [Turin, Italy].

Good therapeutic results with the use of streptomycin and Pasdrazide, a drug in which isoniazid is combined with *p*-aminosalicylic acid (PAS), are reported in patients with renal tuberculosis. The action of this combination, which was always well tolerated, was more marked than that of either drug when used alone. It could be given also to patients who had shown intolerance to *p*-aminosalicylic acid and resistance to it or to isoniazid. Streptomycin and Pasdrazide are indicated for patients with bilateral renal tuberculosis; for those in whom in the presence of bacilluria and pyuria, lesions are not evident on the roentgenograms; for those with forms of superinfection; for the presurgical preparation of patients; and for the postoperative course. Postoperatively, they are a useful adjuvant in the treatment of residual cystitis and they shorten the period in which the patient is bedridden. The medical treatment of renal tuberculosis should be prolonged for one to two years, and courses of therapy should alternate with short treatment-free periods. The authors have adopted the following regimen: 0.5 to 1 gm. of streptomycin and 6 tablets (300 mg.) of Pasdrazide daily for 15 days; then 300 mg. of Pasdrazide daily for 15 days; and then 2,000 units of vitamin D_2, 10,000 units of vitamin A, and one tablet of thiosemicarbazone every day for 15 days. Five such cycles of therapy should be given during the first year and four during the second. Despite the good effects of this medical therapy, the organism's defense reaction, together with rest, a good diet, and the climate, plays a great role in bringing about recovery in patients with renal tuberculosis.

Further Studies on Absorption Through the Human Bladder. N. S. R. Maluf. J. Urol. **73**:830-835 (May) 1955 [Baltimore].

At the urologic surgical service of the Veterans Administration Hospital in Houston, two patients who were ideal for the study of absorption through the human bladder were observed. They had undergone abdominoperineal resection of the rectosigmoid for carcinoma of the rectum. After several months they were readmitted with dyspnea, nausea, vomiting, generalized edema, oliguria, uremia, advanced acidosis, and hyperkalemia. Cystoscopy disclosed bladders with practically normal lining and no invasion by tumor. There was advanced bilateral hydronephrosis owing to near-complete low ureteral obstruction. These findings and the known history of the patients indicated bilateral ureteral obstruction secondary to extension of adenocarcinoma of rectum. Palliative cutaneous ureterostomy was performed in both patients. Diuresis set in promptly after release of the ureters from obstruction, and the postoperative course was smooth. Urinary drainage was through 18 F whistle-tip latex catheters in the dilated ureters. The studies described were carried out during the six weeks to four months after the ureterostomy. When cystoscopy was repeated after this lapse of time, the lining of the bladder was still free from tumorous invasion. Essentially the same technique was used as had been employed during a previous study. A known volume of isotonic sodium chloride solution was introduced into each bladder. After four hours the volumes in the bladder were unchanged and the alterations in total Na^+ and Cl^- in the bladder were within the limits of error. The author's previous observation that there is practically no net absorption of water, Na⁺, or Cl⁻ from an isotonic solution of sodium chloride in the bladder was thus confirmed. Other tests revealed that Na⁺ and Cl⁻ were absorbed through the bladder from hypertonic sodium chloride solution, and water simultaneously entered the bladder. There was no significant net absorption of K⁺ or Cl⁻ through the bladder from moderately hypertonic potassium chloride solution. Urea was absorbed appreciably through the bladder from a hypotonic solution of urea. Water was simultaneously absorbed from the bladder. Dextrose was not appreciably absorbed through the bladder. Water was not absorbed appreciably from moderately hypotonic glycine. Urokon (Na 3-acetylamino-2,4,6-triiodobenzoate) was absorbed through the bladder from high concentration and capable thereby of yielding an excellent pyelogram. I⁻ was absorbed through the bladder from sodium iodide in high concentration. A weak pyeloureterogram can thus be obtained. Plain water, introduced into the bladder, is absorbed slowly. These data are all explicable by simple diffusion.

Hypernephroma and Polyglobulism. H. Gros. Medizinische No. 19, pp. 706-708 (May 7) 1955 (In German) [Stuttgart, Germany].

The rare simultaneous occurrence of hypernephroma and polycythemia is described in a 53-year-old man who had had intermittent macrohematuria for one year when he was admitted to the medical clinic of the University of Mainz, Germany. He had pains in his left side and a flushed face. The erythrocyte count was 7,500,000 per cubic millimeter; the hemoglobin level was 125%; the leukocyte count was 6,300 per cubic millimeter; and the platelet count 160,000 per cubic millimeter. The urine contained many erythrocytes. A large, hard tumor with a fairly smooth surface was palpable in the left upper abdominal quadrant. It extended almost to the umbilicus but also was palpable in the left renal region. A tentative diagnosis of hypernephroma was made with the aid of pyelography. Nephrectomy was performed and a hypernephroma with the typical structure of Grawitz's tumor was removed. On discharge from the hospital the erythrocyte count was 3,300,000 per cubic millimeter, and the hemoglobin level was 68%. The blood count and color of the face remained normal for three years after the operation and the patient was considered cured. Only three similar cases were collected from the literature. Hematuria of prolonged duration was the initial symptom in all these patients. The author agrees with other workers that the cause of the polycythemia, which occurred simultaneously with the hypernephroma and which disappeared with the removal of the tumor, must have been in the kidney and its tumor. A cause and effect relationship is highly probable, but its mechanism cannot be explained. Hematuria associated with polycythemia may result from congestion or renal infarction, while hypernephroma as a rule may be associated with anemia. The possibility of hypernephroma should be considered in the differential diagnosis of polycythemia associated with hematuria, and urologic examinations should be performed accordingly.

Diagnosis and Treatment of Pyelonephritis in Diabetes Mellitus. G. E. Joron, J. deVries, G. Reid and others. Diabetes 4:99-103 (March-April) 1955 [New York].

Autopsies have revealed pyelonephritis in 18 to 22% of diabetic patients, in contrast to 3 to 4% of the general population. Clinicians do not diagnose pyelonephritis nearly so frequently, because diabetic patients may not present the usually described picture of acute pyelonephritis with chills and lumbar pain. Frequency and burning on urination may be absent or, if present, attributed to the diabetes. In most patients there are no subjective symptoms or physical signs to direct attention to an infective process involving the kidneys. In order to establish criteria for the clinical diagnosis of pyelonephritis and to assess the methods of treatment, the authors obtained specimens of bladder urine from 409 diabetic patients and from 280 nondiabetic controls. Catheter specimens of urine were obtained in women, and midstream voided specimens in men. Micro-organisms were found in the urine of 61% of diabetic patients (men and women) compared with 59% of male and 43% of female control patients. This high incidence of infection in men of both groups was unexpected, but may perhaps be accounted for by the advanced average age of the patients, which was 56 years in the men and 60 years in the women. Pyuria was found in 19% of the diabetic men and in 25% of the diabetic women compared with 9% in the control patients of both sexes. Forty-one patients with positive cultures of bladder urine but without urinary complaints were cystoscoped, and cultures of ureteral urine and retrograde pyelograms were obtained. The results suggest that pyelonephritis is present or likely to develop if the same organism is recovered repeatedly from the bladder urine, particularly if there is associated pyuria. Pyelography was of little help in the diagnosis of pyelonephritis. Three types of pyelonephritis are recognized clinically: (1) chronic pyelonephritis without evidence of renal damage or systemic toxicity, (2) chronic pyelonephritis with evidence of renal damage or systemic toxicity, and (3) acute pyelonephritis. For the patients without evidence of chronic pyelonephritis the authors recommend a two-week course of treatment with a suitable antibacterial agent. At the end of this period some will be cured. If not, the course may be repeated in special circumstances, but it seems unwise to pursue therapy indefinitely in every case, because many patients have chronic urinary tract infection for decades without much evidence of harm. In the patients with evidence of renal damage, the authors used prolonged treatment with frequent sensitivity tests and a variety of antibacterial agents. Treatment often increased the patient's sense of well being, even before there was any change in urinary findings. The treatment of acute pyelonephritis must be intensive from the start, since the disease may rapidly become fatal.

INDUSTRIAL MEDICINE

Hydrocortisone in the Treatment of Ganglia. R. E. Rich. J. M. Soc. New Jersey **52**:260-261 (May) 1955 [Trenton, N. J.].

It has been shown that excessive muscular exercise stimulates the tissue in close proximity to joints and tendon sheaths, and that this may cause inflammatory irritation, degeneration, and cyst formation. This being a rational explanation of the cause of a ganglion, the use of an anti-inflammatory substance such as hydrocortisone was tried and found to reverse the process that initiates ganglion formation. An isotonic sodium chloride suspension of hydrocortisone acetate containing 25 mg. per cubic centimeter is injected directly into the ganglion without any attempt to aspirate fluid. The skin is sterilized with 70% alcohol, but no local anesthetic is used. The author prefers the 25-gauge needle, ½ in. long. After injecting the hydrocortisone into the ganglion, a small dressing is applied, and the patient can then return to regular work. The amount of hydrocortisone injected depends on the size of the ganglion. The author rarely injects less than 0.3 or more than 0.5 cc. of hydrocortisone suspensions. The patient is examined daily, and in rare cases a new injection may be required after an interval of one week. The author found this treatment helpful in his capacity as a plant physician at a lamp factory where the operators are mostly women who perform finger, hand, and wrist motions many times daily, with resultant increase in the number of ganglions.

Pulmonary Changes Developing in Workers in the Aluminum Industry. F. Géher. Fortschr. Geb. Röntgenstrahlen **82**:598-604 (May) 1955 (In German) [Stuttgart, Germany].

In studying hygienic conditions in the aluminum industry, Géher examined about 1,000 workers, who were employed in one bauxite mine, in two plants producing aluminum oxide (alumina), and in two alumina-reduction plants. In examining the workers, special attention was given to the occupational history and to respiratory symptoms. Workers with active tuberculosis and with other serious organic disorders had been excluded from working in the aluminum industry by preemployment examinations. Each worker was subjected to thoracic fluoroscopy, and roentgenograms were made whenever there was the slightest suspicion of a pulmonary lesion. Two types of pulmonary lesions were observed, but these do not constitute definite stages of aluminosis, the one more or less merging into the other. Unilateral or bilateral fine strand-like shadows and some pale foci characterize the first type, whereas in the second type the foci are closer together and confluent within the denser areas. The author found that aluminosis developed in 3.5% of the workers exposed to bauxite dust, 4.9% of those exposed to alumina dust, and 6.3% of the workers in the reduction plants, who inhale both alumina and cryolite dusts. No progression was noted in the aluminotic lesions during two years of observation. Since none of the workers was exposed to the inhalation of the dust of metallic aluminum, the author had no occasion to observe the more severe lesions produced with this form of exposure. In contrast to the results of previous investigations, the author believes that inhalation of alumina produces pulmonary changes, but their rapid progression is improbable as long as the working environment does not deteriorate, that is, if the dust counts are kept down.

Roller and Wringer Injuries: Clinical and Experimental Studies. M. A. Entin. Plast. & Reconstruct. Surg. 15:290-312 (April) 1955 *[Baltimore].*

This report is based on experimental investigations and on clinical experiences. Redistribution of electrolytes was determined in the muscles of rats at different times after roller injury of hind legs. The rats showed a loss of potassium and a pronounced gain of sodium. These changes suggest cellular damage. Experimental study of the effect of hyaluronidase on roller injury supports the conclusion that, if it is used early and in sufficient doses, it will curtail edema and reduce the loss of tissue. The group of patients included in this study was selected from a series of cases of roller and wringer injuries, because each demonstrated a different type of avulsion injury with one or several associated injuries. The author saw most of the patients within a short time after injury. Surgical procedures and, in some, definitive reconstruction were begun on the average within four hours after the accident. Rapidity in closing wounds reduces infection and increases the chances of primary healing, both of which are essential to the functional restoration. In some patients injuries occurred in small towns and definitive treatment was not available or was not sought for days or even weeks. Such delays reduce the chances of optimal recovery of function and make the reconstructive procedures more difficult. The degloving and palmodorsal types of injury associated with the loss of part of a member are the more mutilating and reconstructive procedures are, consequently, more difficult and may require several operations. Good function always takes precedence over the cosmetic appearance. Palmar avulsions, even in the very young, are associated with severe injury to the soft tissues and muscles of the thenar and hypothenar eminences. Unless they are frankly ischemic, attempts to preserve partly avulsed palmar flaps should be made by suturing them into the normal anatomic position. The use of primary definitive reconstruction is attended by better chances of success even in patients with severe dorsal avulsion associated with tendon, bone, and joint injuries. Treatment should strive for preservation of all viable tissues, closure without tension, and earliest resumption of motion. Because of the complex nature of some of the injuries, immediate definitive reconstruction may not be possible. The initial treatment, however, must provide complete closure of all wounds without excessive tension in order to minimize stiffening. Unless specifically contraindicated, the placing of the hand in the position of function is imperative. It is important to obtain good primary healing and to start early motion in the hand, because long-standing open wounds, secondary infections, and prolonged immobilization can seriously impair function and interfere with definitive reconstruction. The initial closure of all wounds may entail simple resuturing of the avulsed portion of the skin, application of split-thickness skin graft, or shifting of neighboring skin. In massive loss of skin with exposure of bones and tendons, it may be necessary to apply flaps from distant areas in order to preserve denuded parts and permit future reconstructive operations. When it is possible to combine the initial and the definitive reconstruction, tissue is saved. It is essential to speed up rehabilitation by occupational therapy and by evoking in the patient an enthusiastic desire to regain complete function.

THERAPEUTICS

Studies in Penicillin Hypersensitivity: II. The Significance of Penicillin as a Contaminant. M. Coleman and B. B. Siegel. J. Allergy 26:253-261 (May) 1955 [St. Louis].

Itching of the palms, genitals, axillae, and soles of the feet developed in a 29-year-old nurse 15 minutes after swallowing a 200,000 unit tablet of penicillin. This was followed by itching of the throat and a generalized urticaria and angioedema. A subcutaneous injection of epinephrine relieved most of the symptoms within 30 minutes. One year later this penicillin-sensitive patient was given an intramuscular injection of 25 mg. of an aqueous suspension of testosterone mixed with a small amount of 1% procaine hydrochloride for the correction of menstrual irregularity. A severe allergic reaction with the previous symptoms and in addition with tightness in the chest, audible wheezing, vomiting, and severe lower abdominal pains followed by metrorrhagia was produced in this highly sensitive patient by the use of a supposedly clean, boiled syringe. Complete study by means of passive transfer and direct skin testing revealed negative reactions and no clinical responses to testosterone and procaine. However, when the sterilizer water in which the syringe had been boiled was found to contain penicillin antigen in appreciable amounts, it seemed likely that the contamination of the injectant with penicillin was responsible for the untoward reaction in this patient. Contamination of syringes and sterilizer water with penicillin presents a serious problem, as it is difficult to wash the syringe clear of penicillin and prolonged boiling does not completely inactivate the antigenic principle of the drug. It is hazardous to administer any type of injection to patients who are known to be markedly sensitive to penicillin unless it is certain that the syringes to be employed are not contaminated with penicillin. Allergic reactions in penicillin-sensitive patients, which are commonly attributed to nonantigenic drugs, may in fact be caused by penicillin as a syringe contaminant. The authors' case suggests the possibility that sensitization to penicillin may result from repeated injections of unrelated substances with syringes contaminated with penicillin. To reduce the likelihood of contaminating syringes and sterilizers with penicillin, it is imperative that all-glass syringes and needles be washed at least three times with running water after using. The syringe parts should then be separated before they are placed in the sterilizer. Sterilizers should be cleaned after use and the water in them should be changed frequently and completely. It would be advisable to reserve separate syringes and a separate sterilizer for use with penicillin.

Meticorten and 9 Alpha Fluorohydrocortisone in the Treatment of Allergic Disorders. C. E. Arbesman and R. J. Ehrenreich. *J. Allergy 26:189-200 (May) 1955 [St. Louis].*

Two synthetically prepared steroids, 9-alpha-fluorohydrocortisone and prednisone (Meticorten) were given therapeutic trials in patients with allergic disorders. Eight patients with severe asthma, seven of whom had been symptomatically controlled with cortisone or hydrocortisone, were treated with 2 to 12 mg. of 9-alpha-fluorohydrocortisone daily for 4 to 14 days. Although very effective for sodium retention and eosinophil-reduction response, 9-alpha-fluorohydrocortisone was of no value in the relief of asthmatic symptoms. Prednisone was given to 20 patients, 17 of whom had bronchial asthma, one dermatomyositis, one perennial allergic rhinitis, and one chronic urticaria and angioedema. Of the 17 asthmatic patients, 16 had been on maintenance therapy with either cortisone or hydrocortisone for long periods. Fifteen of these 16 patients obtained at least equally beneficial results from prednisone when 5 mg. of this drug was substituted for each 25 mg. of cortisone and 20 mg. of hydrocortisone. In one patient severe epigastric pain developed with 10 mg. of prednisone; he was switched back to hydrocortisone without difficulty or ill-effects and remained well. The 17th asthmatic patient had not previously had steroid therapy and obtained excellent relief with an initial daily dose of 20 mg. of prednisone for one week. He continued to improve on a maintenance dose of 10 to 15 mg. daily. The patient with dermatomyositis was more satisfactorily controlled by prednisone than by hydrocortisone. The patient with severe perennial allergic rhinitis and the one with giant urticaria and angioedema failed to respond to prednisone. Prednisone, despite no supplemental potassium or sodium restriction, did not affect these electrolytes in patients with the doses used by the authors. Prednisone did not affect the blood pressure or body weight. Prednisone is clinically four to five times as effective as cortisone and three to four times as effective as hydrocortisone, milligram for milligram. The long-term effect of this new steroid must yet be determined. The usual precautions and contraindications of the other steroids should be observed. Prednisone, like the other steroids, is not a substitute for specific management of the allergic or asthmatic patient.

Recent Viewpoints on the Pharmacology of Narcotine. H. Konzett. Wien. klin. Wchnschr. 67:306-309 (May 6) 1955 (In German) [Vienna, Austria].

Narcotine, a benzoylisoquinoline derivative and one of the secondary alkaloids of opium, was given in doses of 0.5 to 1 mg. per kilogram of body weight to cats in which attacks of cough were produced by mechanical stimulation of the mucosa of the trachea. The cough reflex was controlled surprisingly well. This effect of narcotine was similar to that obtained with codeine. The lungs of the anesthetized cats were then subjected to rhythmical inspiration with the aid of Starling's respiration pump. The amount of air which with a constant maximum inflation pressure could no longer be taken up by the lung was directed to a volume-recording instrument, by which it was quantitatively recorded during the inspiration phase. This method permits quantitative measurements of bronchoconstrictor as well as of bronchodilator effects. With the use of this technique narcotine proved to exert a moderate bronchodilator effect when doses of 2 to 4 mg. per kilogram of body weight were given. Narcotine caused slight lowering of blood pressure of short duration. This effect depended primarily on vascular dilatation. Narcotine also exerted a weak spasmolytic effect on isolated strips of small intestine and colon obtained from rabbits and guinea pigs. It also exerted a spasmolytic effect on the stomach and intestine of the intact animals. Experiments on dogs that were given narcotine daily for 13 weeks showed that the cough-inhibiting effect remained the same despite the prolonged therapy; drug habit, therefore, did not develop. Cough was induced by inhalation of citric acid aerosol in healthy persons and in patients with asthma who then were given narcotine and codeine in tablets. Narcotine in doses of 5 to 15 mg. exerted a definite cough-inhibiting effect that was stronger than that obtained with larger doses (30 mg.) of codeine. Although further therapeutic trials in man are required for definite evaluation, the conformity in the results obtained in human cough and in experimentally produced cough reflex in animals is noteworthy.

A Clinical Evaluation of Elorine Sulfate. I. R. Schwartz, E. Lehman, J. M. Seibel and others. Am. J. Gastroenterol. 23:461-468 (May) 1955 [New York].

Elorine, a quaternary ammonium compound (1-cyclohexyl-1-phenyl-3-pyrrolidino-1-propanol methsulfate), was given to 167 patients with hypercholinergic gastrointestinal manifestations, 144 of whom were followed up long enough for proper evaluation. Of these 144 patients, 104 had peptic ulcer and 40 had miscellaneous hypercholinergic disorders such as dumping syndrome, functional diarrhea, irritable colon, ulcerative colitis, duodenitis, and psychoneurosis with hypercholinergic gastrointestinal manifestations. Seventy-seven of the 104 patients with ulcers were successfully treated as shown by prompt and sustained relief of symptoms. These patients received 50 mg. of the drug four times a day, and in the more severe cases 75 to 100 mg. was given four times a day. The authors believe that more patients could have been helped by the use of doses larger than the initially recommended 50 mg. four times a day. Twenty-two of the patients in the miscellaneous hypercholinergic group were successfully treated, although the number of patients in each category was not statistically significant. Gastric secretion studies revealed a distinct response in diminution of volume of secretion and of free acid only when the intragastrically installed dose of the drug was 100 mg. or more. Undesirable side-effects were surprisingly moderate in number and severity. Only five patients could not tolerate the drug because of toxic effects. Doses of 75 mg. to 100 mg. four times a day are necessary for therapeutic purposes, but the dose of 50 mg. four times a day can be used as a maintenance dose. Elorine, and Co-Elorine (25 mg. of Elorine sulfate combined with 8 mg. of amobarbital) with its added sedative effect, are valuable additions to the treatment of diseases manifested by hypercholinergic symptoms.

Ultrasonic Therapy with Special Reference to Rheumatic Diseases. F. Friedland. Am. J. Phys. Med. 34:379-385 (April) 1955 [Baltimore].

Compared with the more commonly accepted therapeutic agents such as infra-red and short-wave diathermy, ultrasound seems to have a therapeutic efficacy equal to that of the thermal energies and in some conditions slightly better. In constitutional diseases such as rheumatoid arthritis ultrasound is not curative, but it is a worthwhile adjunct to the total therapeutic regimen. It allows of obtaining improvement in patients resistant to other forms of therapy. It is convenient in application, requiring treatment of from 4 to 10 minutes as compared with 20 to 30 minutes for all other forms of thermal energy. In the treatment of subdeltoid bursitis and rheumatoid spondylitis, ultrasound has the definite advantage over x-ray therapy that it can be used repeatedly for the treatment of unavoidable recurrences. Ultrasound in the recommended doses is believed to be safe. Thus the author prescribes this therapy as first choice in Marie-Strümpell spondylitis, sciatic neuralgia, and subdeltoid bursitis except when certain contraindications exclude its use, e. g., lack of cooperation on the part of a patient who cannot be depended on to report increased pain or burning, the most important safeguard against overdosage and tissue damage. The author also advises against the use of ultrasound before, during, or after the period of x-ray therapy because of the possible summation effect of these two radiant energies.

PATHOLOGY

Diagnostic Study of Serous Effusions with Emphasis on Some Unusual Findings. M. L. Perou and M. S. Littman. Am. J. Clin. Path. 25:467-479 (May) 1955 [Baltimore].

Specimens of serous effusions were obtained from the pericardial, pleural, or peritoneal cavities of 50 patients, both during life and at autopsy. There were 10 control patients with no malignant tumor, 27 patients with carcinoma, 10 with lymphoid tumors, 2 with mesotheliomas, and one with reticuloendotheliosis (Letterer-Siwe's disease). The following practical conclusions can be drawn from the study. 1. Undifferentiated tumor cells cannot be of value in locating the primary site of these cells, whereas well-differentiated tumor cells afford great diagnostic help. 2. Organoid arrangements are pathognomonic of cancer and are better seen in hematoxylin-stained and eosin-stained sections of sediments. Liebow stated: "Occasionally strips of mesothelial cells may curl upon themselves to present a misleading acinar aspect." 3. Carcinoma cells can often be distinguished from sarcoma cells. 4. Certain types of metastasizing carcinoma can be ruled out or confirmed by cytological examinations of serous effusion alone. 5. Certain types of sarcoma such as reticulum cell sarcoma, Hodgkin's sarcoma, and, to a lesser degree, lymphosarcoma can be recognized in serous effusions. 6. Besides mesothelial, inflammatory, and carcinoma cells one may also find sarcoma, reticular cells, or myeloid cells in serous effusions. Too often the cytologist looks only for "carcinoma cells," and the interpretation of the other types of cells present is neglected. 7. Mesotheliomas may be suspected from cytological examination of appropriate serous effusions. The presence of a syncytial pattern or of sarcoma-like cells and carcinoma-like cells side by side seems characteristic although not pathognomonic, since other types of tumor such as anaplastic carcinoma or leiomyosarcoma may give similar findings. The tubular or papillary type of mesothelioma is often indistinguishable from carcinoma of the bronchus, breast, or ovary.

BOOK REVIEWS

Forceps Deliveries. By Edward H. Dennen, M.D., F.A.C.S., Professor of Obstetrics and Gynecology, New York Polyclinic Medical School and Hospital, New York. Obstetrics & Gynecology: A Series of Monographs, edited by Claude E. Heaton, M.D., Associate Professor of Obstetrics and Gynecology, New York University College of Medicine, New York. Cloth. $6.50. Pp. 228, with 88 illustrations. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1955.

This is an excellent summary of modern thinking concerning the most frequent, the most useful, and the most abused operative procedure in obstetrics. In the first two chapters, the author discusses the indications for forceps delivery, the conditions necessary for the safe delivery of the baby and the prevention of trauma to the mother, the classification of forceps operations, correct diagnosis, and proper application of the instrument. Most of the book is devoted to the use of forceps in the delivery of the head in a posterior position or arrested in the transverse, as well as the use of special instruments for special situations. The final chapters are devoted to the Keilland, the Barton, and the Piper forceps and their use under special conditions and indications. The text is illustrated throughout by excellent line drawings that picture the proper application of the various instruments in situations most suited for their use. The author is undoubtedly a superb craftsman who has learned to use the best instrument to meet his special needs. In his introduction he says that "the ultimate object of this book is to show that there is a choice of instrument in delivery with forceps, depending on existing conditions; that one should choose the type of forceps that suits the case rather than try to make all cases fit one type of forceps." Unfortunately, such skilled technicians are a vanishing lot and most obstetricians today are fortunate if they develop real dexterity in the use of one type. Furthermore, many patients in whom a difficult midforceps delivery would have been performed in the past are now delivered by cesarean section and this trend will continue. If forceps delivery is undertaken only when the head is well engaged in the pelvis, there is little use for axis-traction devices to which the author is attached, for the skilled accoucheur can obtain a desirable mechanism of delivery without their use. A favorable delivery mechanism can be carried out easier and all manipulations simplified if an episiotomy precedes the application of the blades. This excellent monograph is recommended for the specialist and the casual obstetrician, but it must be remembered that it is the man behind the forceps and not the instrument that is all important.

The Royal Society of Medicine: The Realization of an Ideal (1805-1955). Written at the request of president and council by Maurice Davidson, M.A., D.M., F.R.C.P. Cloth. 21s. Pp. 201, with 29 illustrations. The Royal Society of Medicine, 1 Wimpole St., London, W.1, England, 1955.

Not often does one find such a thoroughbred book as this one, which was written to commemorate the 150th anniversary of the Royal Society of Medicine. The esteem in which the society is held in British medicine is exemplified in the recognition given it by the sovereigns of Britain since the time of His Majesty King William IV who granted it a charter in 1834 and who thereby declared himself "and his successors if they shall think fit" the Patron of the Society. Each of the successors of William IV has thought fit to be its patron. On what must have been a highly impressive occasion on May 21, 1912, King George V and Queen Mary attended the opening ceremony of the new home of the society at no. 1 Wimpole Street. In November, 1922, the president of the society announced to the council that His Royal Highness the Prince of Wales, having accepted an honorary fellowship, had been unanimously elected. The chapters on the proceedings of the society and especially that on the library, which has been described as the finest medical library in Europe, if not in the Western Hemisphere, will evoke in the reader deep contemplation and nostalgia.

A unique chapter in a book of this sort called the "Presidential Chair" provides a brief account, with illustrations, of those who have occupied the presidential chair beginning with Sir William Selby Church, B.T., K.C.B., M.D., to the present occupant, Sir William Gilliatt, K.C.V.O., M.S., now Surgeon-Gynecologist to Her Majesty Queen Elizabeth II. There should be few who will fail to regard the last chapter on the future as required reading for all members of our profession. Those who are content with the present trend in medicine here and abroad will pause to reflect. Those who are deeply concerned will take fresh courage, despite the risk of being called reactionaries, in maintaining the traditions of the past that elevated the physician in the esteem and affection of the public—a position many have failed to treasure, and, once lost, will in this day be difficult to recapture. Some time ago there were those who were deeply concerned that medicine must choose whether to follow the path of freedom and solid accomplishment or be tempted to turn down a road that would lead to its seduction. It appears to have chosen the latter and consequently finds itself in a maelstrom of corrosive forces that are sapping its strength and dignity.

Those reactionaries that predicted what was to come and those, not familiar with the old road and yet troubled with the new, will derive inspiration and fresh courage from this account of the development of the Royal Society of Medicine. In 1905, the centenary year of the Royal Medical and Chirurgical Society of London, the Chronicles of the Society from 1805 to 1905 were published. Now that the Royal Society of Medicine has reached its jubilee, this chronicle of the events of the society during the last 50 years links the present with the past. The society may well take pride in the constellation of stars among the great clinicians on her roster of bygone days. Their stature is well portrayed in this book, which is in no sense a mere historical account of a medical fellowship. It is published in excellent taste and the illustrations, especially the frontispiece in colors from the drawing by Patrick Hall, are a delight to examine.

Antenatal and Postnatal Care. By Francis J. Browne, M.D., D.Sc., F.R.C.S., Consulting Obstetric Surgeon, University College Hospital, London, and J. C. McClure Browne, B.Sc., M.B., F.R.C.S., Professor of Obstetrics and Gynæcology, University of London, London. Eighth edition. Cloth. $8. Pp. 672, with 94 illustrations. Little, Brown and Company, 34 Beacon St., Boston; J. & A. Churchill Ltd., 104 Gloucester Pl., London W.1, England, 1955.

The introductory chapter gives the development of antenatal care. The presentation of data reveals the slow but gradual progress of the evaluation of better obstetric care, with the lowering of maternal mortality. Credit is given to various countries for their contributions in this direction. The sequence of chapters begins with the diagnosis of pregnancy. Subsequently, emphasis is given to the medical examination. Evaluations of special points are made in regard to diet, hygiene, general care, travel, bathing, care of the breasts, articles of clothing, and smoking. One chapter by Grantly Dick Read presents the emotional aspect of pregnancy and parturition. Three chapters are devoted to hemorrhage. The conditions in the first of these are abortion, tubal gestation, fibroid polyps, cervicites, varicosities, and carcinoma. The second chapter on hemorrhage deals with hydatiform mole. The third has to do with habitual and recurrent abortion. Thirty pages are devoted to hemorrhage of late pregnancy, primarily placenta previa. A second chapter on hemorrhage of late pregnancy discusses abruption of placenta.

The nature and manner of presentation implies authority, skill, and competence of the authors. Their knowledge of the literature of obstetrics commands respect. Much of the discussion involves biology, heredity factors, sex, Mendelian characteristics, and other useful information. The classification and number of medical complications, such as anemia, chorea, polyneuritis, myasthenia gravis, and syringomyelia, are listed separately. The methods for diagnosis are advanced logically. The recommendations for treatment are consistent and current.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

The section on venereal and related diseases gives appropriate coverage to syphilis and gonorrhea. Moderate space is given to trichomonas infection and mycoses. The therapies of these two latter conditions derive more from Europe than from the Western Hemisphere. The section on radiology and obstetrics is profusely documented by pictures and illustrations, but only 20 pages are given to postnatal care. The book makes little mention of care on parturition. The book is valuable for the proper attitude with which the material is presented and the broad coverage and the healthy discussion of the normal and abnormal conditions in the prenatal period.

Gynæcology. By Douglas H. MacLeod, M.S., F.R.C.P., F.R.C.S., Gynæcological Surgeon, St. Mary's Hospital, and Charles D. Read, M.B., F.R.C.S., F.R.A.C.S., Director, Institute of Obstetrics and Gynæcology, British Postgraduate Medical Federation, University of London, London. [Formerly Eden and Lockyer's Gynæcology.] *Section on Anatomy* by James Snyder, M.D., F.R.C.S. *Section on Physiology* and Endocrinology by Russell Fraser, M.D., F.R.C.P. *Fifth edition.* Cloth. $16. Pp. 864, with 551 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1955.

The first edition of this book, which was popular many years ago, was written by Eden and Lockyer and published in 1916. These authors prepared revised editions in 1920 and 1928. The fourth edition was revised by Whitehouse in 1935 and now, after 20 years, the fifth edition appears. Because the present authors believe that many data that were in the edition of 20 years ago are still accepted as orthodox gynecologic opinion and practice, they have made few alterations in the sections dealing with the clinical aspects of infection, ectopic pregnancy, simple uterine tumors, and gynecologic diagnosis. They have made great changes in the chapters on endocrinology, antibiotics and chemotherapy, blood transfusions, early diagnosis of cancer, infertility, and pathology. Special chapters were written by James Snyder on anatomy, Russell Fraser on physiology and endocrinology, and H. Hulbert on radiotherapy. The authors say the space devoted to operative gynecology is limited because the field cannot be covered properly except in a special textbook. In discussing the complete exenteration operation, Brunschwig's paper and statistics of 1949 have been quoted even though he has written several articles since then. It is unfortunate that few of the references quoted in the section on guides to further reading are to recent articles. Those quoted for diverticulitis are of 1907, 1916, 1917, 1925, 1926, and 1930. The reference for urethral diverticula is of 1890. In spite of this minor criticism, the book is outstanding. It is ably written by two of the foremost gynecologists in the world. There is an enormous amount of useful information about gynecology. The advice given about therapy is excellent and in accord with that recommended in the United States as well as Great Britain. The illustrations are numerous and well reproduced. The authors are to be commended for having brought this great book up to date and for having improved it immeasurably.

The Halogenated Aliphatic, Olefinic, Cyclic, Aromatic, and Aliphatic-Aromatic Hydrocarbons Including the Halogenated Insecticides: Their Toxicity and Potential Dangers. By W. F. von Oettingen, M.D., Ph.D., United States Department of Health, Education, and Welfare, Public Health Service, National Institutes of Health, National Institute of Arthritis and Metabolic Diseases. Public Health Service publication no. 414. Cloth. $2.50. Pp. 430, with illustrations. Superintendent of Documents, Government Printing Office, Washington 25, D.C., 1955.

This book is a review of the accumulated knowledge on the mechanism and action of the halogenated hydrocarbons. Carbon tetrachloride, DDT, Freon, methyl bromide, and other less familiar chemicals used as insecticides, solvents, fumigants, and refrigerants are described. The chemistry, analytical procedure, potential uses, investigative toxicology, clinical toxicology, and the prophylaxis and treatment of poisoning from them are discussed. Since many of these compounds are finding increasing use in industry and our daily life, this synopsis of their toxicology is intended to reduce the incidences and facilitate the diagnosis and treatment of poisoning and stimulate research on many unanswered problems concerning their activity. As a reference guide to help further knowledge on newer poisons used in industry and in agriculture, this book can be highly recommended.

Origins of Resistance to Toxic Agents: Proceedings of the Symposium Held in Washington, D.C., March 25-27, 1954. Edited by M. G. Sevag, Department of Microbiology, School of Medicine, University of Pennsylvania, Philadelphia, Roger D. Reid, Head, Microbiology Branch, Office of Naval Research, Department of the Navy, Washington, D. C., and Orr E. Reynolds, Director, Biological Sciences Division, Office of Naval Research, Department of the Navy. This symposium, organized by editors, was held under joint auspices of Office of Naval Research and University of Pennsylvania. Cloth. $12. Pp. 471, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1955.

The discovery of sulfonamides and various antibiotics has been considered by some as having introduced the golden age in therapeutics. This was predicated on the optimistic belief that infectious diseases were about to become a thing of the past, but disappointment and concern among physicians about the increasing resistance to antibiotic therapy now prevails. This book offers a serious warning against any false sense of security regarding the control of infections with this group of compounds. Toxic reactions involving systemic and metabolic derangements, dermatological manifestations, and hypersensitivity are an added and rather discouraging development. These and other challenging problems prompted the organization of this symposium, which brought together various specialists, principally for discovering the common element in an apparent diversity of ideas. The book is divided into five parts. The first is devoted to resistance of microbicides to drugs, its origin and mechanism. The second part explores resistance to herbicides and insecticides. Insect resistance to DDT has been analyzed intensively as to the source, distribution, and causes for resistance and its difference from other insecticides. The origin of tolerance and addiction to drugs and the special problem of alcoholism is discussed in part 3. The biochemical and physiological disturbances associated with addiction to drugs, as well as psychological and sociologic factors, are reviewed. Part 4 examines resistance factors common to infectious agents and cancer cells. It discusses transformations to resistance and dependence of leukemic cells, the nature of tumor immunity, and factors in resistance to infectious diseases. The physiological, chemical, and genetic factors involved in resistance are reviewed in part 5. This book is an authoritative report on a complex subject, the full implications of which are still undetermined.

The Management of Obstetric Difficulties. By Paul Titus. Revised by J. Robert Willson, M.D., M.S., Professor of Obstetrics and Gynecology, Temple University School of Medicine. Philadelphia. Fifth edition. Cloth. $12.50. Pp. 737, with 349 illustrations, C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1955.

Willson has reduced the size of the book by more than 300 pages. The large section on infertility has been retained, although it has been drastically cut. It is questionable whether infertility comes under the heading of obstetric difficulties. Extensive changes have been made throughout the book. Outmoded, unproved, and many controversial procedures have been omitted, but the book remains essentially what Titus intended it to be, hence it is not in competition with the conventional textbooks on obstetrics. Willson emphasizes that local infiltration anesthesia is simple, safe, and effective for providing pain relief for the mother without affecting the infant, yet at Temple University Hospital over 12,000 spinal anesthetics have been administered for delivery and no woman has died or been permanently injured as a result of the procedure. Willson says that extensive hormone therapy is not often necessary during pregnancy, but in some women the endocrines may be helpful. He questions the beneficial effects of estrogen or progesterone in abortion, and he says that neither estrogen nor the male hormone needs to be given to inhibit engorgement of the breasts after delivery. The section on the newborn infant was written by Victor C. Vaughan III. The book is well written and contains much valuable information and advice. The latter is practical and conservative. The illustrations are numerous, clear, and instructive, but the colored frontispiece, which was drawn 20 years ago and shows the Friedman-Lapham modification of the Aschheim-Zondek test, should be omitted from the next edition. This book has been popular, and the improvements made by Willson will undoubtedly increase its popularity. The publishers also deserve praise for having done their part well.

Progress in Allergy. IV. Edited by Paul Kallós. Contributors: M. G. Bohrod, et al. Cloth. $20. Pp. 520, with 149 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6, 1955.

In his introduction to this fourth volume Kallós gives an excellent review of the current progress in allergy in addition to covering facts that are well known. The student of allergy will find this introduction together with the large bibliography a valuable source of information for laboratory or clinical use. Each contributor is outstanding in his particular field. The manner in which the various facets of clinical and basic scientific concepts of allergy has been presented is excellent.

Bohrod's contribution on histology of allergic and related lesions is a comprehensive review of the histopathology of allergic disorders. In it he attempts to correlate the lesions described by the clinician and immunologist as allergic with the pathological findings. This article is one of the best discussions available on this subject. Mayer's chapter, entitled "Group-Sensitization to Compounds of Quinone Structure and Its Biochemical Basis," is well documented. Those interested in this subject will be well rewarded by reading it. Delayed hypersensitivities are discussed by Raffel. The most important recent advances in allergy concern the adrenal steroids. Three of the contributors have dealt with different phases of this problem. Experimental asthma is ably discussed by the Noelpps, and Maunsell has a chapter on respiratory allergy to fungus spores that includes the classification, identification, diagnosis, testing, therapy, and culturing of molds. All in all this book is a worthwhile compilation.

Minor Surgery. By John E. Sutton, M.D., F.A.C.S., Assistant Clinical professor of Surgery, Cornell University Medical College, New York. Handbooks for General Practitioner. Cloth. $7. Pp. 334, with 102 illustrations. Landsberger Medical Books, Inc.; distributed by Blakiston division of McGraw-Hill Book Co., Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1955.

The author was confronted by the eternal problem of differentiating between major and minor surgery. He considers minor procedures those concerned with simple uncomplicated conditions that do not endanger the patient's life or future health. This excellent book is written in a succinct style with a lack of redundancy. Chapter 6 gives an outstanding discussion of the problems of "antimicrobials," an aptly applied term. Intelligent and effective use of these agents depends on ascertaining the clinical diagnosis and the identity of the organism responsible for the infection. The advocacy of general anesthesia in the office or home is questionable to those who practice in areas well supplied with hospital facilities, but we must bear in mind our neighbors who do not have such advantages. A greater number of illustrations would enhance the value of this work. This book should be a valuable asset to the general practitioner and can be recommended to anyone interested in minor surgery.

The Pharmacological Basis of Therapeutics: A Textbook of Pharmacology, Toxicology, and Therapeutics for Physicians and Medical Students. By Louis S. Goodman, M.A., M.D., Professor of Pharmacology, University of Utah College of Medicine, Salt Lake City, and Alfred Gilman, Ph.D., Professor of Pharmacology, College of Physicians and Surgeons, Columbia University, New York. Second edition. Cloth. $17.50. Pp. 1831, with 89 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1955.

This book needs little introduction for it has maintained its popularity as a pharmacology textbook despite the fact that 14 years have elapsed since the first edition was published. The present edition is much larger than its predecessor, as might be expected from the many advances in clinical pharmacology during the past decade. Emphasis is placed on the evaluation of new drugs and particularly on the necessity for cautious acceptance of preliminary therapeutic claims. As in the first edition, much space is devoted to discussing the relationship of chemical structure and pharmacological activity. As with any book of this type some portions are already out-of-date, but this does not detract from the essential value of this book in acquainting the physician and medical student with the newer drugs as well as with the basic principles necessary for the rational use of drugs in clinical practice.

Atlas der Haut- und Geschlechtskrankheiten. Von Dr. Walter Frieboes und Dr. Walther Schönfeld, o. Ö Professor und Vorstand der Universitätsklinik und Poliklinik für Haut- und Geschlechtskrankheiten Heidelberg. Second edition. Cloth. 118 marks; $28.10. Pp. 292, with 476 illustrations. Georg Thieme, Herdweg 63, (14a) Stuttgart, Germany; (agents in U. S. A. and Canada, Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16), 1955.

This volume admirably fulfills the function of an atlas. It contains 470 excellently selected illustrations, all but a few of which are true color reproductions of the commonly encountered diseases and many of the uncommon. They are contained in one volume and arranged in a logical manner. Each page contains three or four close-up illustrations showing the essential character of the lesions with but a minimum of explanatory text in German. The volume, of excellent stock, is well indexed. The outstanding features, however, are the excellence of the colored illustrations and the large number of them. It is unfortunate that the high cost of production makes it impractical to publish a book of this kind in the United States.

Physiology and Anatomy with Practical Applications. By Esther M. Greisheimer, M.A., Ph.D., M.D., Professor of Physiology, Temple University School of Medicine, Philadelphia. With the assistance of Ann A. Miraldo, R.N., B.S., Science Instructor, Temple University School of Nursing. Seventh edition. Cloth. $5. Pp. 868, with 478 illustrations. J. B. Lippincott Company, East Washington Sq., Philadelphia 5; Pitman Medical Publishing Company, 39-41 Parker St., Kingsway, London, W.C.2, England, 1955.

The present edition of this popular book for nurses continues to present the essentials of anatomy and physiology in a lucid, easily understood manner. Much material has been rewritten, revised, and reset. Among other changes the section on the nervous system has been condensed into two chapters, one dealing with the peripheral (including the autonomic) and the other with the central nervous system. The chapter dealing with the endocrine system has been completely recast. The addition of new illustrations serves to facilitate assimilation of text material. Situations, with relevant questions, follow each chapter. Nursing students should find this book a real aid.

Clinical Endocrinology for Practioners and Students. By Laurence Martin, M.D., F.R.C.P., Physician to Addenbrooke's Hospital, Cambridge, and Martin Hynes, M.D., M.R.C.P., Clinical Pathologist to Royal Northern Group of Hospitals, London. Foreword by Sir Lionel Whitby, C.V.O. M.C., M.D., Regius Professor of Physic, University of Cambridge, Cambridge. Second edition. Cloth. $5.50. Pp. 253, with 39 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1., England, 1954.

This book is divided into 11 chapters on the pituitary; Fröhlich's syndrome and obesity; the pineal body; the thyroid gland; the parathyroid glands; the thymus; the adrenal glands; the testes; the ovary; the breast; and hormone implantation. It is written in excellent English with few excess words. It contains an astonishing amount of useful information. Most American endocrinologists will not take issue with the opinions expressed. It should be a useful addition to the library of those practitioners whose interest is not primarily in the field of endocrinology. Because of its brevity, the information sought can usually be quickly obtained.

Differential Diagnosis of Internal Diseases: Clinical Analysis and Synthesis of Symptoms and Signs on Pathophysiologic Basis. By Julius Bauer, M.D., F.A.C.P., Clinical Professor of Medicine, College of Medical Evangelists, Los Angeles. Second edition. Cloth. $15. Pp. 987, with 65 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1955.

This edition includes some of the newer approaches and a great deal of philosophical thinking regarding the interpretation of symptoms. The author deplores the indiscriminate use of such tests as angiography of the heart or brain, aortography, and biopsies of the liver and kidney. This text is well written and the print and type of paper are excellent. The bibliography covers the most important references to the subjects discussed. This book should make an excellent addition to the library of anyone who is interested in the interpretation of symptoms and signs.

QUERIES AND MINOR NOTES

ANTIBIOTICS USED LOCALLY

To the Editor:—*Is the application of Aureomycin powder to wounds an approved procedure? Formerly the sulfonamides were so used, but it is believed this method was discarded as ineffectual and only the systemic administration of the sulfonamide drugs favored.* M.D., *California.*

Answer.—There is some divergence of opinion as to whether Aureomycin powder should be applied topically to wounds. This difference of thought extends to the local application of other antibiotic agents. However, most authorities do not recommend the local application of any antibacterial agent to fresh wounds, including those of the peritoneal surfaces. Their opinion has been formed as the result of several observations. Topically applied agents usually have a short period of bacteriostasis due to their absorption. They may be locally irritating, because of either their pH or chemical structure. They may also cause a state of hypersensitivity to the agents used, thereby depriving patients of the future benefits of these agents. In addition, there is tissue culture evidence that some of the antibiotics, including Aureomycin, inhibit the proliferation of epithelial cells in relatively low concentrations. The local application of antibiotic agents, particularly over long periods of time, favors the acquisition of resistance by bacteria to the agents used. This is causing the development of resistant strains of bacteria in our environment that are beginning to produce infections not influenced by any of the available agents. It is, therefore, recommended that antibiotics, which are safe and effective for systemic use, not be used topically. If the use of an antibacterial agent is deemed necessary, one of the agents not likely to be used parenterally, such as Neomycin, Polymyxin, or Bacitracin, should be chosen.

VARICOSE VEINS DURING PREGNANCY

To the Editor:—*A 30-year-old white woman is 24 weeks pregnant with her fourth pregnancy. She had varicosities of the right thigh and vulva with the last pregnancy, with almost complete disappearance of these postpartum. Now there are moderately severe varicosities of the right thigh and to a lesser extent of the lower leg. Those of the right vulva and buttock are painful due to distention after standing. Please advise, particularly on the advisability of using an elastic stocking. Benjamin E. Morgan, M.D., Wilson, N. C.*

Answer.—Women who have varicose veins of the legs and thighs should keep their legs on a chair or a stool while they are sitting. This relieves the distended veins of the extra load of blood they must carry when the feet are lowered in the usual position. Care must be exercised not to injure varicose veins because they may bleed or become infected. When the veins are unusually large a rubber stocking or elastic bandage must be worn. The stocking or bandage should be long enough to extend above the highest visible varicose vein and should be put on the leg in the morning before the wearer arises. In the case cited, a rubber stocking will compress the veins in the lower leg but not the veins in the upper thigh, vulva, and buttocks. A tight panty girdle can relieve painful varicosities in the vulva and buttocks. In many cases the veins may be obliterated by injection treatment during pregnancy. The results of this type of treatment are good and the dangers slight, if any. Special care must be taken during labor to prevent lacerations of the varicose veins in the vulva.

APLASTIC ANEMIA FOLLOWING DRUG THERAPY

To the Editor:—*A woman, 50 years of age, developed aplastic anemia following treatment with Butazolidin. When the patient was first seen, Dec. 1, 1954, she was acutely ill, with 1,670,000 red blood cells per cubic millimeter and a hemoglobin level of 5.05%. No bone marrow was found on sternal puncture, and there were no platelets. The patient is at the hospital receiving daily treatment of 25 units of corticotropin (ACTH), 5% glucose in water, and transfusions of whole blood. On December 27, 1954, there were 3,570,000 red blood cells per cubic millimeter; the hemoglobin level was 11.15; and there were no platelets. The patient has no complaints and feels as well as ever. What is the prognosis, and can anything be added to the present treatment; also, need corticotropin be given daily, as her veins are becoming sclerosed? Melville V. Popelar, M.D., Cincinnati.*

Answer.—The prognosis of aplastic anemia due to marrow pancytopenia associated with drug therapy is always grave. Such cases have been reported to follow the administration of Butazolidin. In general partial or complete recovery from well-established drug-induced refractory anemia is unusual but possible after a period of weeks or months. It has not been convincingly shown to be accelerated by any method of treatment. As spontaneous recovery may occur, the opportunity for it to develop is obviously increased by prolonging the survival of the individual. Regular transfusions of whole blood or of packed red blood cells in order to maintain the hemoglobin level in the vicinity of 10 gm. per 100 cc. are the most useful therapeutic measure. In this patient orally administered cortisone should be substituted at once for intravenously given corticotropin so that the patient may leave the hospital if conditions for home convalescent care under close professional supervision are satisfactory. Corticotropin and cortisone are probably equally effective in preventing purpuric bleeding by decreasing vascular fragility and sometimes in addition by elevating the platelet count. There is little evidence for a beneficial effect of either on red or white blood cell production in such patients. In rare instances of hypoplasia of erythropoiesis, especially in children, cortisone has increased the erythroid cellularity of the bone marrow. The anemia has then become responsive to vitamin B_{12}. Splenectomy is probably contraindicated because of absence of platelets and marrow megakaryocytes unless red blood cell survival is short.

The patient probably also has leukopenia with few granulocytes. As long as a minimal number of adult polymorphonuclear cells are in evidence, leukopenia does not often lead to infection. Chemotherapy, such as for an infection of the oral cavity, should be reserved for a clinical indication and not used prophylactically. On an empirical basis, to guarantee the adequacy of nutritional factors for erythropoiesis, the patient should receive a nutritious diet and in addition 30 mcg. of vitamin B_{12} every two weeks by injection as well as 1 to 5 mg. of folic acid daily by mouth. Based largely on vague clinical impressions, the patient might be given in addition daily 1 unit of Liver Extract or Liver Solution U. S. P. daily by mouth if these crude liver preparations are well tolerated.

TRACHEOTOMY TUBE

To the Editor:—*What effect would a few drops of 2% bicarbonate of soda have on mucus that plugs up a size 1 tracheotomy tube in situ? What is the chemical reaction? Anchise A. Cirillo, M.D., Jamaica, N. Y.*

Answer.—Two per cent sodium bicarbonate of soda has a very mild detergent reaction on mucus. Its use would be somewhat beneficial in cleaning a tracheotomy tube. A few drops instilled into the tracheotomy tube in situ from time to time is practiced in many institutions.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

MENTAL DISORDERS AND THYROID EXTRACT

To the Editor:—*1. What is the rationale for the treatment of mental disorders, other than those associated with severe hypothyroidism, with very large doses of thyroid extract? 2. Is there any danger in the daily intake of 5 to 20 grains (0.3 to 1.2 gm.) of thyroid extract for months or years?*

M.D., Illinois.

Answer.—1. For patients who have mental disorders but who do not have definite hypothyroidism, there probably is no real rationale for the use of thyroid extract. Although there have been reports on the use of large doses of thyroid extract in the treatment of mental disorders in the absence of hypothyroidism, such medication has not been commonly used. Danziger and Kindwall in 1948 suggested that mental disorders are related to depression of cerebral metabolism. They also suggested that the ingestion of thyroid extract would increase the cerebral metabolism. 2. There is danger in the daily intake of 5 to 20 grains of thyroid extract. In general, a euthyroid patient can tolerate larger doses than one who has myxedema, but the tolerance may vary widely in both groups of patients. For a majority of patients with myxedema, the disease will be well controlled with a dose of thyroid extract (U. S. P.) ranging somewhere between 1 and 2½ grains (0.065 to 0.10 gm.) daily. The patient who has a normal or lowered basal metabolic rate but without evidence of myxedema may tolerate twice this amount or more. A daily dose of 20 grains of thyroid extract (U. S. P.) would, however, be very likely to produce symptoms of hyperthyroidism in members of either group.

THROMBOCYTOPENIA IN INFANT

To the Editor:—*A newborn infant developed thrombocytopenia on first day of life. He was a first-born child and had bleeding from the intestines and genitourinary tract into skin and into the cerebrospinal fluid. With supportive therapy, he recovered completely. Other causes for bleeding were ruled out, and the platelet count was 30,000 per cubic millimeter. The parents were free from any manifestations of disease. Harrington has shown that such cases are apparently due to the passage of platelet agglutinins from mother to child; the parents wonder what likelihood there is that subsequent children may have similar trouble.* *M.D., Ohio.*

Answer.—There are two types of thrombocytopenia in the newborn infant. In the first, the mother shows thrombocytopenia purpura due to an acute platelet agglutinin that is then transmitted from the mother to the infant. In the second type, the mother may develop antibodies against the infant's platelets which then enter the infant's circulation, causing thrombocytopenia similar to the mechanism existing in hemolytic anemia of the newborn infant. The frequent thrombocytopenia in hemolytic anemia of the newborn infant is probably also caused by the same mechanism. Apparently, the case in question belongs to the second category. Although no reports discussing this problem on a larger scale are yet available, it is known that frequently thrombocytopenia may occur in several infants in the same family.

POLIOMYELITIS

To the Editor:—*1. What effect would the simultaneous administration of antipoliomyelitis gamma globulin have on the effective stimulation of antibody response elicited by the Salk vaccine? 2. At the age of 2½ years a patient had polioencephalitis. She now is 4 years old. Could it be possible that she has a natural immunity to poliomyelitis and does not need the Salk shots?* *M.D., New York, and M.D., Ohio.*

Answer.—1. None. 2. If the diagnosis of polioencephalitis was correct, then the patient is immune to the type of virus that caused the attack. There are three types of poliomyelitis virus, and the patient may not be immune to the other two types. The only way to determine this would be to do neutralization tests for all three types of virus with serum collected from the patient.

CASTRATION

To the Editor:—*Will bilateral orchiectomy render an adult male sexually impotent, or is there a possibility of endocrine contributions from other glands supplying the stimulus necessary to coitus? Would such castration aid in deterring the compulsion to commit "sex crimes" of mutilation of children or abuse of children or horror crimes on adult members of society usually classed as "sex maniac crimes"?*

M.D., Michigan.

Answer.—Castration in a male adult leads usually to a decrease in sexual libido to a varying extent, but there is often sufficient sexual potency remaining to perform coitus quite satisfactorily. Castration in a prepubertal male results in almost complete impotency. The adult male retains his neuromuscular reflexes for coitus in spite of castration and not because of the contribution of androgens from other glands such as the adrenals. This operation would probably deter an individual from sex crimes, on a purely hypothetical basis.

SURGICAL SKIN PLANING

To the Editor:—*Where may I get information about surgical skin planing?* *M.D., Ohio.*

Answer.—An article on surgical skin planing for the improvement of acne scars and other types of pitting appears in the *A. M. A. Archives of Dermatology* (68:389 [Oct.] 1953). In surgical skin planing, the operator anesthetizes and temporarily stiffens the skin with a spray of ethyl chloride and then abrades and removes with a revolving wire brush the layer of skin projecting above the base of the acne scars. Usually two or three treatments at monthly or bimonthly intervals will improve the scars considerably. Occasional bad sequelae from this procedure are: (1) hyperpigmentation, especially in dark-skinned individuals, which may persist for a long time; (2) skin erythema, especially in light-skinned individuals, which may take three to six months to disappear; (3) numerous milia in the area operated on, especially after two or three treatments; and (4) scarring in areas where the planing has been carried too deeply.

PENICILLIN

To the Editor:—*Can the ordinary type of repository penicillin be used orally? To do this one would take aqueous procaine penicillin in 10 cc. vial (penicillin G) containing 3,000,000 units, remove it from the vial, and dilute it for the desired amount per teaspoonful, the diluting being done with water.*

Edward S. King, M.D., Shelby, N. C.

Answer.—It should be possible to use procaine penicillin in this way. Several of the commercial preparations of penicillin tablets for oral administration contain procaine penicillin rather than soluble penicillin. This method should result in some saving in cost to help offset the inconvenience involved. It should be realized that procaine penicillin administered by mouth does not possess the advantage of long action that it has when injected parenterally. The possibility of more rapid loss of potency with more dilute suspensions would have to be guarded against as well as inaccurate dosage because of less stable suspensions unless dispersing agents were added to the diluent.

CARE OF TRACHEOTOMY PATIENTS

To the Editor:—*What, if any, deleterious effects might occur from the use of methyl cellulose preparations, similar to that used in patients with dry eyes, if this were instilled into the trachea of a person in whom laryngectomy has been done to moisten the tracheal mucosa?*

Jim Vaughn, M.D., Tyler, Texas.

Answer.—References could not be found in the medical literature on the use of methyl cellulose in handling tracheotomy cases. In the early postoperative period following tracheotomy or laryngectomy, the following solution may be used to moisten the trachea and loosen thickened secretions: Terramycin (aqueous) 500 mg., Alevaire solution, 20 cc. and isotonic sodium chloride solution 80 cc. This is kept in a dropper bottle. One or 2 cc. is instilled into the trachea before and after each tracheal aspiration. Suction catheters are sterilized each time they are used. If secretions are very thick, tenacious, or crusting, 125,000 units of Tryptar is added to this solution as an enzyme digestant. For the chronic care of a patient in whom laryngectomy has been done occasional irrigation with a mixture of Alevaire and sodium chloride solution should be adequate.

POSTANESTHESIA GRANULOMAS

To the Editor:—*A patient who was severely burned about the back had extensive skin grafts for which she was given an anesthetic intratracheally. The intratracheal tube was in place for about six hours. Shortly after the anesthetic the patient developed a choking sensation. A laryngeal examination revealed two large granulomas, one on the right cord and one on the left cord, occupying almost the entire posterior third of the cords. Under direct laryngoscopy both granulomas were removed with biting forceps, obtaining apparently clean cords. The papilloma on the left cord has recurred and has been removed three times since. At the present time the papilloma on the left cord is small but definitely present. Would x-ray therapy be a value of treating this patient, or should the granuloma be treated as it has been in the past, by surgical removal?* *M.D., New York.*

Answer.—The terms "granuloma" and "papilloma" are used interchangeably, although they are two distinct clinical entities. From the history, it is assumed they are postanesthesia granulomas. Occasional laryngoscopic removal when the lesions cause a voice problem is the treatment of choice. X-ray therapy would be of no value. A period of two weeks silence following surgical removal is recommended.

ERUPTION ON LOBES OF EAR

To the Editor:—*A woman has itching of the ear lobes, accompanied by swelling and weeping of the skin. This was attributed to earrings of the clamp type. Recently it has been noted that the reaction of the ear lobes has occurred after the application of Wood Violet cologne, and a similar reaction has occurred in the bend of the elbows where the material was applied. Please comment and name the constituent that may be the offender.*

Lester Adams, M.D., Greenwood Mountain, Maine.

Answer.—The eruption described is no doubt due to the cologne. It is difficult, however, to say which of its constituents may have caused the eruption. Nevertheless, in some patients it is the oil of bergamot, although others of the constituents may have contributed to the eruption as well. Further, it is difficult to obtain the exact formula of many of these proprietary preparations. A contact dermatitis due to the use of cologne is not infrequently seen, and exposure to the sun would seem to accentuate it. Concerning prevention, in addition to the avoidance of contact with any colognes insofar as possible, some of the antihistaminics have been successful in decreasing the threshold, but these have not been completely successful in full desensitization.

SCIATICA

To the Editor:—*What is the present accepted treatment of acute uncomplicated sciatica of "rheumatic origin"? If Thiamine hydrochloride still is one of the best remedies for this pathology, what doses would you suggest? Is the administration of antibiotics of definite benefit?* *M.D., Ohio.*

Answer.—Acute uncomplicated sciatica of "rheumatic origin" is present in certain cases of rheumatoid arthritis or spondylitis. In any event, treatment should be directed toward the arthritis, and a careful search should be made for the cause of the sciatica. Eradication of the cause of the sciatica should be attempted. This may have to be surgical. Thiamine is useful only if the sciatica is part of the picture of thiamine deficiency; otherwise the administration of thiamine does not help.

RHEUMATOID ARTHRITIS

To the Editor:—*A 23-year-old tractor mechanic has complained for five months of early morning tingling, pain, and swelling of both hands, not related to the position of sleeping and relieved after a few hours by heat and exercise. Physical examination (except for some coldness of the fingers), urinalysis, hemoglobin level, and sedimentation rate are normal. The symptoms are prevented by small doses of cortisone but not by aspirin. Will this patient develop more typical rheumatoid arthritis?* *L. D. Baxter, M.D., Hatch, N. Mex.*

Answer.—This patient's symptoms are consistent with rheumatoid arthritis in an early stage, but a definite diagnosis of this condition is not justified in the absence of objective joint swelling. It is likely that he will develop more definite signs of rheumatoid arthritis, although the possibilities remain of a spontaneous remission of symptoms or the continuance for months or even a few years of what has been termed the prodromal phase of the disease. Cervical ribs should be ruled out by roentgenograms. Symptoms of this nature could also be caused by sleeping with his arms over his head, the so-called hyperabduction syndrome. It would seem preferable not to employ cortisone until the diagnosis has been made with certainty. Treatment should consist of additional rest, a more than adequate diet, and the use of heat and aspirin.

GENERAL PARESIS

To the Editor:—*What percentage of people with general paresis or taboparesis would show a negative blood Wassermann and Kahn?* *D. H. Smith, M.D., Warren, Pa.*

Answer.—The percentage of individuals with syphilitic involvement of the central nervous system with negative serologic tests for syphilis will depend on the duration of the disease, the amount of previously administered therapy, and the sensitivity of the serologic procedure employed. The statistics vary considerably, but in general it is believed that the blood Wassermann and Kahn tests, with present-day sensitivity, will give 98 to 100% positive reactions in untreated paretics and 70 to 85% positive reactions in untreated tabetics.

BRUCELLOSIS

To the Editor:—*May I compliment the author of the answer to the query on brucellosis in* The Journal *(158:705 [June 25] 1955). The reply shows an unusual understanding of the problem of chronic brucellosis, including use of desensitization by heat-killed Brucella organisms and the frequent need for psychotherapy in these cases, in order to facilitate recovery. The only part of the reply that is open to question is the statement that "the most effective anti-Brucella therapy is a combination of dihydrostreptomycin or streptomycin and tetracycline given over a period of at least two weeks." Probably the desire to condense the reply led the author to this dogmatic-sounding statement. Actually, the most effective suppressive therapy varies a great deal in different patients. In some, streptomycin and sulfadiazine (or triple sulfonamides) appears to be most effective, bringing about apparent cure in several patients who have remained well for nine years after its use. In still others any of the wide-spectrum antibiotics are effective, depending on the patient's tolerance and clinical response. Even the narrower-spectrum erythromycin exerts a suppressive effect in a large number of patients and may have the advantage of fewer and less severe side-effects. The most effective method in my experience, in the chronic disease, is desensitization with subtolerance doses of heat-killed Brucella abortus vaccine, alternating or concomitant with one or more antibiotics and sulfonamides. Failure of actual cure in many may be due to intracellular growth and reproduction of Brucella, as demonstrated by Buddingh and Goodpasture and by Castaneda and others.*

EVALUATING A MEDICOLEGAL OFFICE

AUTOPSY INDEX AS A COMPARATIVE STANDARD

Henry W. Turkel, M.D., San Francisco

There is wide and general agreement that 20 to 25% of all deaths require medicolegal investigation.[1] There is little or no agreement on what percentage of these medicolegal cases require autopsy. Some medicolegal officers perform autopsies on all of these cases; others perform it on none.[2] Regardless of the percentage on whom he finds it necessary to perform an autopsy, each officer will tell you that in his jurisdiction there is little or no danger that criminal and violent deaths will be overlooked. Moreover, he believes that in natural deaths a correct and satisfactory cause is given. The causes and circumstances of deaths in various jurisdictions do not vary in any such degree as the variation in percentage of autopsies performed would seem to imply. It is apparent that either some medicolegal offices are doing too few autopsies or perhaps others are doing too many. It is certain that some objective basis need be sought for establishing the percentage of cases that might need an autopsy in order to achieve safe standards of medicolegal practice. Once these are established there would then be available a means of evaluating the level of practice in any given community. Where the standards are being met there would be far more assurance that deaths by crime and violence are not passed over.

Heretofore, it has been rather arbitrarily decided that of all the cases coming into the medicolegal officer's jurisdiction 20% require autopsy.[3] As might be expected, such information arose from those most active in the field. Generally, the percentage they find acceptable is at or below the percentage they find themselves performing in their own jurisdiction. Such basis for setting standards is wholly unsound. Each area has different problems, such as budget and finance, pressure from outside interests, and resistance to autopsy by religious and business groups. Also, depending on the laws existing in the area, more or less autopsies need to be done to meet the legal requirements. Above all, the personal interest of the medicolegal officer profoundly affects the number of autopsies done. With these factors influencing the number of autopsies done, any percentages so established can only reflect what seems practically attainable in a given area or what appears satisfactory to a particular medicolegal officer. There is nothing to assure that such percentages are either medically or legally adequate.

AUTOPSY INDEX

In the past it has been customary to judge an office, in part, on its autopsy rate, i. e., the percentage of medicolegal cases given autopsy. Actually, to say that an autopsy rate is 10% or 100% is utterly meaningless in itself. A medicolegal officer may choose to declare as medicolegal problems only a few of the most outspoken cases. This might amount to as little as 2% of the total deaths in his community. If now, he performs autopsies on all of these relatively few cases, he will present a 100% autopsy rate, yet he has investigated but the smallest portion of what he should investigate, and surely there is much he must be overlooking. Another officer may accept 25% of all deaths in his community for investigation. If he performs autopsies on one-half of these, he will present a 50% autopsy rate. Despite the lower rate in this second instance, the medicolegal officer has more fully and properly discharged his duties. Accordingly, the autopsy rate can be seen to be a deceiving and confusing figure that should be abandoned. In its place is recommended the "autopsy index":

$$\frac{\text{no. of medicolegal autopsies}}{\text{total deaths in the community}} \times 100 = \text{autopsy index.}$$

It is an expression of the ratio of medicolegal autopsies not to the number of medicolegal cases but rather to the

total number of deaths in the community. This latter is a given quantity, uninfluenced by the medicolegal officer, and is therefore a far more reliable standard. On inspection the autopsy index will be recognized simply as a percentile ratio. Admittedly, the autopsy index tells nothing of the extent of investigation at the scene. It does not evaluate the care and thoroughness of the autopsy. It provides no measure of the use of the microscope or laboratory. *Despite this, it is held that an autopsy is the only certain way to find a true cause of death.* It is the medicolegal officer's most important and useful scientific tool. The fact that it is being used affords the greatest measure of probability that correct causes of death are being found. The necessary information to calculate the autopsy index is available to anyone, simply by examining the local or state health department statistics.

TABLE 1.—*Classification of Deaths Requiring Autopsies*

	No.	% of 400 Coroner Cases *	% of All Deaths in County †
Violent Deaths			
Relationship of trauma to death			
Uncertain or undetermined			
1. Possible criminal liability of another	39	9.7	2.4
2. Possible civil liability of another..	25	6.2	1.5
3. No apparent liability..............	18	4.5	1.1
Believed evident			
4. Possible criminal liability of another	26	6.5	1.6
5. Possible civil liability of another..	17	4.3	1.1
6. No apparent liability..............	29	7.2	1.8
Other	14	3.5	0.9
Nonviolent Deaths			
No known medical attention past year			
7. No information on health status or events before death..............	65	16.2	4.0
8. Believed in good health by acquaintances; no knowledge of events before death................	19	4.8	1.2
9. Believed in ill health by acquaintances; no knowledge of events before death..........................	21	5.2	1.3
10. Acquaintances or witnesses describe symptoms suggesting natural death	47	11.7	2.9
Under treatment or treated past year			
11. Physician states death unexpected or unaccountable....................	33	8.2	2.0
12. Physician states not unexpected; no witnesses to events before death	18	4.5	1.1
13. Physician states not unexpected but not recently in attendance; symptoms described by witnesses suggest natural death.............	29	7.2	1.8

* Total of 2,350 coroner cases, 1954.
† 9,750 deaths in county, 1954.

PRESENT STUDIES

The San Francisco coroner's office accepts as coroner's cases 24% of all deaths in the county. This meets the needs prescribed by virtually all authorities. Also, in all these cases autopsies are performed by certified or board-eligible pathologists. Each case is investigated at scene by a full-time trained deputy. Among other ings, the deputy takes notes at the scene, examines for vidence of external trauma, interrogates witnesses, and makes a search for evidence or history of medical treatment. His detailed report includes statements taken from any physicians known to have been treating the deceased or from hospital records. A series of 400 consecutive coroner's cases was reviewed. The cases were broken down into groups according to the detailed circumstances of the death. Also, the number found in each group was translated into the percentage of total deaths in the community that the group represented. Then, in the subsequent discussion, each group was evaluated to determine whether the cases in that group would reasonably need autopsy to safely and properly establish the cause of death. The groups requiring autopsy were also gathered together and totaled according to whether they fell into one of the three following classes: (1) crime or suspicion thereof, (2) violence or casualty, and (3) *no history of medical attendance. This* last grouping is of importance since some states require investigation of death in class 1 only. Others require an investigation of classes 1 and 2. Still others require investigation of deaths in all three. Taking in account what is legally required in any given state, the number of medicolegal autopsies that might be needed for safe standards of practice can be approximated in relation to total deaths in a given area (table 1). In many jurisdictions certain of the groups listed in table 1 would be signed out with the presumed cause of death. *Particularly is this true of* cases without evidence of trauma and with some history to suggest previous illness. Table 2 shows the number and type of errors that would have been made had the presumed cause of death been used. This could be shown because in all these cases there was available the actual cause of death as determined at autopsy.

CRIME OR SUSPICION THEREOF

When there is a possibility of criminal liability (groups 1 and 4), an autopsy must be done. It makes no difference that the means or cause may appear evident on the surface. The courts rightfully require that not only the cause of death shall be available to them but also the exact mechanism shall be known. If any doubt remains, the defense will capitalize on it to the extent that justice may not prevail. There must be proof beyond any doubt that the deceased did in fact come to his death by the criminal instrumentality presumed to have been used. The vaguest possibility that some other cause or contributing factor played a part must be ruled out or at least clarified. Of even greater importance is the responsibility to see that, no matter what the apparent cause of death, no one should be prosecuted, much less convicted, unless there are clear and certain medical findings to prove that his act did actually cause the death. Criminal cases of this order account for 4% of the total deaths in a community.

A sizable number of deaths occur without previous medical attendance and with no information on events preceding death (groups 7 and 8). Most are instances of persons who were already dead when found. In the absence of external trauma these deaths are, in many jurisdictions, presumed to be of natural causes, and are usually signed out without autopsy. Generally, the death certificate is filled out with some commonly encountered but highly technical cause of death. Such impressive diagnosis as "hypertensive and arteriosclerotic heart disease" will no doubt satisfy a lay observer. Actually though, the circumstances would permit no more of a conclusion than perhaps that this is a "presumed natural death." Such a cause of death on a certificate would be reason for its rejection by the local registrar. A correct statement of the cause of death is obviously expected and, in fact, is required.[4] An outright fabrication of a cause of death is intellectually dishonest. Indeed, it is even less exact than the many-year-old and much ridiculed "just plain died." The latter, while to be condemned, tells us more or what was actually known than does a medical diagnosis fabricated without basis.

An even more important reason to perform autopsies in these cases can be seen in table 2. Of 232 deaths presumed by the evidence to be natural, 8 (3.5%) actually were due to violence and 6 more were due to contagious and reportable disease. The causes in these violent deaths were asphyxia, poisoning, traumatic intracranial hemorrhage, laceration of the brain with skull fracture, intratracheal foreign body, and accidental carbon monoxide poisoning without external evidence. The contagious cases are of importance since their being reported is of concern in the general public welfare. There is reasonable cause to believe that these groups (7 and 8) should have autopsies. They constitute 5.2% of all deaths. In group 11 the physician in attendance has stated that he is unable to arrive at the cause of death or that the death was unexpected. It is unreasonable to presume that another person, physician or not, should simply review the same history or view the body and be able to arrive at the cause of death. Without doubt these cases, comprising 2% of all deaths, must have autopsies.

In groups 9 and 12 there is knowledge of the preexisting illness. However, no creditable person has seen the deceased for some time before his death nor is there knowledge of events preceding the death. Persons with long-standing illness may well die of that illness and frequently do. But, they also may die of any of the causes from which healthy persons die. In the absence of medical attention it is foolhardy to simply presume that they must have died of their preexisting ailment simply because they were known to have hypertension, cardiac disease, or even carcinoma. As a matter of fact, the proportionate incidence of certain types of violent death is higher in this group than in the general healthy population. Unless there is conclusive evidence at the scene to assure beyond all reasonable doubt that the preexisting illness did cause the death, the officer is being unduly lax if he fails to investigate fully. Such conclusive evidence at the scene is uncommon. Any less caution in such cases suggests that he is seeking and taking the easiest way out rather than fulfilling his duty. While this way out generally meets with the approval of the surviving family and even, at times, with the physician's approval when the family is pressing him, it is neither safe nor accurate. These cases constitute 2.4% of all deaths and should have autopsies.

In all of the foregoing groups there is a reasonable possibility that crime or violence will be exposed by autopsy. There is, in all, a significant element of doubt. They total 13.7% of all deaths. Thus, in a state that requires that criminal and suspicious deaths shall be investigated, a minimum autopsy index of 13.7 should be maintained to assure safe standards.

VIOLENCE OR CASUALTY

Groups 2 and 5 include those cases in which there appears to be some civil liability on the part of another. Many civil court proceedings revolve about medical testimony on the cause of death. The total monetary value of court judgments that are thus both granted and denied is huge. Of comparable size is the sum total of insurance company claims paid or denied. It is a matter of great public concern that these should be decided fairly. It is the medicolegal officer's responsibility and duty to see that the true facts are provided. Many millions of dollars are spent maintaining the civil courts so that justice will prevail. By comparison, the cost and amount of work in performing the necessary autopsies would be negligible. So doing would eliminate injustices, and, above all, it would do much to decrease the instances of fraud that may frequently be perpetrated by plaintiffs and claimants. Equally, it can assure that in deaths wherein the civil liability of others is unknown to the surviving family, the autopsy findings may afford the first knowledge of this. It can prove of the utmost significance in the welfare and circumstances of the survivors in providing them with their rightful due.

TABLE 2.—*Number and Type of Errors Had Autopsy Not Been Performed*

No Evidence of Violence or Trauma, Death Presumed Natural	
At autopsy	
Proved as natural	218
Proved as violent	8
Proved natural but contagious	6
Total	232
Evidence of Violence or Trauma	
At autopsy	
Proved as violent	91
Proved as natural	51
Remains uncertain	12
Total	154

Table 2 shows that of 154 deaths possibly due in whole or in part to violence or casualty, 51 (30%) proved due to natural causes. These findings not only relieve a significant number of individuals of unjustified civil liability; they equally relieve many who might otherwise feel moral responsibility for the death. Violent or casual deaths involving civil liability only amount to 2.6% of all deaths, and these should have autopsies. Thus, in any state requiring investigation of violent and casual deaths as well as criminal and suspicious deaths, a minimum autopsy index would be 16.3.

INSUFFICIENT MEDICAL HISTORY

Those deaths presumed to be nonviolent, to which there were lay witnesses who can describe the symptoms or events before death—are tabulated in groups 10 and 13. It rests in the medicolegal officer's judgment to decide whether he will accept these descriptions as adequate for determining a cause of death. That a person complained of pain in the chest or abdomen, or simply collapsed at home or at work before witnesses, is hardly sound basis for a conclusive cause of death. A cause of death based on such evidence is inexact both technically and medically. From the experience gained in maintaining a high autopsy index, it is certain that without such autopsies many violent deaths would be overlooked. Such findings as pulmonary embolus, aspiration of foreign body, head injury, and poisoning are not uncommon in these cases. These account for 4.7% of all deaths. Thus, in a state requiring investigation of death by crime or violence or casualty and also all deaths occurring without medical attendance, a minimum autopsy index of 20.7 would be required.

---

[4] Physician's Handbook on Death and Birth Registration, ed. 10, U. S. Dept. of Health, Education and Welfare, Public Health Service, 1949. 83rd Congress, Title III of Public Health Service Act, Section 312a.

SOME ASPECTS OF AUTOPSY INDEX

Highest Standards.—Despite that the remaining 4% of all deaths have no apparent liability of others, they nonetheless deserve consideration. On the surface, suicides by jumping from heights, by hanging, or by overdose of medication are reasonably evident. It is advisable to assure that no other agent was involved or that the person was not already dead before the scene was prepared to simulate a suicide. Particularly is this necessary in the absence of handwritten notes that can be checked. Deaths by fire, anesthetic deaths, surgical mishaps, errors in therapy, and deaths in institutions complete the group. The ultimate in scientific accuracy and in the discharge of responsibility to the public is attained by an autopsy index of 23 to 25.

Need for High Index.—Some will argue that only an occasional case would be uncovered by such high standards, perhaps not enough to justify the work and expense. While this is not true, for the moment I will concede that only a few such cases are discovered. Often many thousands of dollars of public funds, as well as limitless effort, are spent in prosecuting a single major criminal case. Why should that much not be spent to find out another? Why should the crime as yet unrecognized be totally ignored? Why should the criminal escape unpunished? Certainly it is inconsistent to go to such ends in one crime and disregard another because of similar cost or effort. Moreover, the cost is not comparable. The service to the public in detection and prevention of crime, in the adjudication of civil matters and in contribution to the general public welfare many times outweighs the considerations of the cost or effort in performing these autopsies. Furthermore, once the administrative machinery and personnel are set up to handle a given number of autopsies on a given budget, an increase of, let us say, 10% autopsies does not increase the budget by 10%. It would indeed be much less than 10%.

Feasibility.—To some it may appear that an autopsy index of 20 cannot be achieved. It is often said that because of public resistance to autopsies it simply would not be tolerated. This is wholly without basis. In California 14 of the total 58 counties maintain an autopsy index of 20 or better.[5] Some are as high as 30. This is clear evidence that high standards can be attained in both urban and rural areas, providing that the medicolegal officer has the determination and courage to do so. One might wonder whether there is something special about the California law that permits such standards. In essence it is the same as in most every other state.[6] All states authorize investigation of criminal and suspicious deaths. Virtually all require investigation of violent or casual death. The majority make it the legal duty of the medicolegal officer to certify all deaths in the absence of an attending physician. (Even if not specifically provided in the law, practically everywhere, the medicolegal officer is the one called upon to certify the cause of death in such instances.) By no mere chance, these also are the basic provisions of the California law. It would appear that in almost any state it is possible, though not necessarily certain, that high standards could be met.

Application.—Despite the admirable standards maintained in many California counties, the average autopsy index in the state is 13.2. This is an unduly low figure. A review of health department statistics[5] reveals that the low average is attributable to one or two heavily populated jurisdictions that maintain the alarmingly low autopsy index of 10 or less. A knowledge of this permits directing attention and seeking improvement precisely where it is needed. Once made aware of their comparative failing, there is reasonable probability that, with sufficient urging and support, these few jurisdictions could be improved. Bringing them up to standard is far the easiest approach and would provide a statewide level of practice fully acceptable and in this case, second to none. This could be applied to many other states and indeed should be done.

Causes of Low Index.—Having established a minimum acceptable autopsy index for any given area, any lesser value suggests failing on the part of the medicolegal officer. He is yielding to expediency, bending under pressures applied, or is bound by budget matters. Indeed, he may be plagued by all three. It is frequently said that there is a general lack of public concern. It is often held that resistance to autopsies by the public and by morticians is insurmountable. These must be more apparent than real. In the 14 California counties that maintain an autopsy index above 20, the public is spending the necessary money and the morticians are amenable to such standards of practice. Neither the public nor the morticians are that much different in the counties with poor standards than they are in those with high standards. There is reason to believe that in any area acceptable standards can be achieved. To gain public support in any jurisdiction where it is lacking requires a firm and conclusive basis for comparison. First, it must be established, on sound consideration, that improvement is needed; second, it must be shown exactly where the improvement is needed; and, third, the urgency and importance must be demonstrated. It is believed that the autopsy index can serve well in these regards.

SUMMARY AND CONCLUSIONS

Four hundred medicolegal cases were classified in groups according to the nature and circumstances of death. From this information it was then decided which of these groups might reasonably require autopsies to properly establish the cause of death. From these tabulations it was determined what proportion of the total deaths in the community would need autopsy to maintain safe standards of medicolegal practice. This quantity is termed the "acceptable autopsy index." The following minimum acceptable autopsy index is suggested for the various states according to their respective laws:

---

[5] Statistics of State of California, Department of Public Health, Death Records, 1953.

[6] Coroners in 1953: A Symposium of Legal Bases and Actual Practice, New York National Municipal League, March, 1954.

Criminal or suspicious deaths only	13.7
Criminal or suspicious deaths and deaths by violence or casualty	16.3
Criminal or suspicious deaths, deaths by violence or casualty, and deaths with no history or recent medical attendance to afford true cause	20.7
Highest desirable standards	25.0

It is believed the vast majority of states have laws adequate to permit a thorough investigation and autopsy of a much higher proportion of medicolegal cases.

The result of this study shows the pressing need for this greater number of autopsies and offers some medical and legal basis to justify their performance. It is suggested that the most practical and reasonably accurate means of evaluating the standards of medicolegal practice in any given community is by use of the "autopsy index." This requires observing the number of medicolegal autopsies performed in relation to the total deaths in the community. This is in preference to the current practice of simply noting the percentage of autopsies performed on medicolegal cases. This obviates the confusion that results from a medicolegal officer certifying very few deaths in the community as medicolegal problems and performing autopsies on a large percentage of these. While the percentage is high in the later instance, actually, few cases have been investigated. The quantity $\frac{\text{no. of medicolegal autopsies}}{\text{total deaths in the community}} \times 100$ is termed the "autopsy index." It is a valuable measure of the level of practice in any given area when compared to other areas or to certain stated standards. Relatively few communities meet the requirements of a minimum acceptable autopsy index.

650 Merchant St. (11).

EFFECTIVENESS AND COMPLICATIONS OF NEEDLE BIOPSY OF THE LIVER

Dennis A. J. Morey, M.D., Robert L. Means, M.D.
and
Kemp Plummer, M.D., Richmond, Va.

One hundred thirty-nine needle biopsies of the liver have been carried out at the Richmond Veterans Administration Hospital over the past eight years by means of the Silverman needle through either an abdominal or a transthoracic approach. All the biopsies were performed for diagnostic purposes on 119 patients whose final diagnoses, established by clinical, biochemical, and histological evaluation or at autopsy, were as follows:

Laennec's cirrhosis	69
Fatty metamorphosis, due to alcoholism	4
Carcinoma, primary or metastatic	26
Granulomas	3
Leukemia	3
Obstructive jaundice	2
Primary amyloidosis	1
Toxic hepatitis	1
No hepatic disease	10

EFFECTIVENESS

Nineteen biopsies failed to reveal the diagnosis finally established, so that the incidence of failure was 13.8%. In only two cases was the failure due to insufficient biopsy tissue. Metastatic carcinomas accounted for 12 of the cases, primary hepatomas 2, portal cirrhosis 4, and granuloma 1. It is evident that 15 of the 19 missed diagnoses occurred in cases in which there were focal lesions, i. e., carcinomas and granuloma. Fourteen of these cases were among the 31 in which ultimately primary or metastatic carcinomas were demonstrated at autopsy, operation, or subsequent needle biopsies, an error of 45.2%. Four biopsies failed to show a histological picture of portal cirrhosis, an incidence of 4.6%. The tissue obtained in each case was that of normal liver or possessed only minor changes that would not warrant a pathological diagnosis of cirrhosis. This error was presumably due to needling a well-regenerated nodule of hepatic cells and failure to obtain adequate amounts of interlobular tissues.

COMPLICATIONS

Hemorrhage was the only severe complication encountered. It occurred in four cases, in one of which the patient died. One patient experienced a transient fall in blood pressure to 90/60 mm. Hg but recovered uneventfully and required no transfusions. This biopsy was performed with an abdominal approach and revealed moderately severe fatty metamorphosis. His prothrombin time was 38%.

Two patients bled profusely into their peritoneal cavities, causing shock and necessitating blood transfusions. One of these patients had a primary hepatoma superimposed upon marked portal cirrhosis. The biopsy specimen was obtained by the abdominal approach. His prothrombin time was 75%. One week after biopsy 800 cc. of bloody fluid were obtained by a midline abdominal paracentesis. The second patient had chronic myelogenous leukemia, which was demonstrated in the liver tissue obtained by transthoracic biopsy. Prior to biopsy, his prothrombin time was 30%, but it was raised to 60% by the administration of vitamin K_1 intravenously. Eight hours following biopsy the patient went into shock and showed evidence of peritoneal irritation. Seven pints (3,312 cc.) of whole blood were administered as well as vitamin K_1 daily, without evidence of cessation of the

bleeding. Meanwhile, a prothrombin consumption time of 20% was demonstrated and, after a single transfusion of 500 cc. of fresh whole blood, bleeding ceased and he recovered uneventfully. The single death was due to severe intra-abdominal hemorrhage and irreversible shock. The patient had severe Laennec's cirrhosis, and the biopsy specimen had been obtained by the transthoracic route. This patient's prothrombin time had been 33% prior to biopsy, and, at autopsy, a well-defined puncture hole was seen in the liver, without evidence of laceration.

These cases represent an incidence of hemorrhage of 2.9% and a mortality rate of 0.72%. It is interesting to note that two of the hemorrhages occurred with the abdominal approach, an incidence of 1.7%, whereas, two cases of hemorrhage occurred with the transthoracic approach, an incidence of 10.5%. The remainder of the patients tolerated the procedure without ill-effects, except for 16 patients who complained of transient pain localized at the site of biopsy that occurred within 24 hours of the biopsy and required, at most, one dose of a narcotic. Of these, only two had prothrombin times below 50%. Twelve of the biopsies had been performed by the abdominal approach, an incidence of 10%, whereas four were performed by the transthoracic route, an incidence of 21.1%.

COMMENT

In 139 needle biopsies of the liver performed on 119 patients the diagnosis was effectively made in 86.2%. Diagnoses were missed in 19 cases, in only 2 of which was the error due to failure to obtain sufficient tissues. Fifteen of these errors occurred in patients with focal hepatic lesions consisting of 12 metastatic carcinomas, 2 primary hepatomas, and 1 granuloma. These cases represent only a small percentage of the total number in which biopsies were done but constitute 45.2% of the total number of cases of primary and metastatic hepatic carcinomas. This is a considerably higher incidence than that reported by Safdi and co-workers,[1] in which needle biopsies failed to demonstrate neoplasms in only 12 of 53 patients, an incidence of 22.6%. The higher incidence of missed diagnoses in our study may be due to the fact that the presence of metastatic neoplasms within the liver was not established in several cases until three to six months later, and conceivably the neoplasms may not have been present at the time of the original biopsies.

Four cases of "diffuse" hepatic disease were missed, an incidence of 4.6% of the total number of cases in which biopsy of cirrhotic livers was done. In each case, an adequate core of liver tissue was obtained that histologically revealed normal hepatic cells, with little or no interlobular tissue. In such instances where adequate gross tissues are obtained but microscopically only normal hepatic cells are seen in the absence of any periportal supporting tissue, the possibility of a regenerated hepatic nodule should be entertained and emphasis accordingly placed upon the degree of cellular regeneration and the architectural distribution of the cells.

The complications encountered in this study consisted of 4 hemorrhages, with one fatality, and 16 cases of transient abdominal pain requiring a single dose of narcotic, with disappearance of symptoms within 24 hours. The one death represents a mortality rate of 0.72%, which is far in excess of the incidence of 0.085% established by Zamcheck and Klausenstock[2] in their study of 20,016 needle biopsies of the liver. In this relatively small study, however, it cannot be considered statistically significant and no doubt is an example of the "error of small numbers."

Zamcheck and Klausenstock,[2] from data obtained by personal communication with Klatskin, reported no complications in 82.6% of 352 liver biopsies, pain requiring analgesics in 13%, fall in blood pressure in 1.4%, and low blood pressure requiring transfusion in 0.8%. In comparison, our experience may be summarized as follows:

No complications	85.6 %
Pain requiring analgesics	11.5 %
Fall in blood pressure	0.72%
Low blood pressure requiring transfusion	1.44%

Analysis of the prothrombin times obtained in the patients with complications reveals that in three of the four who had hemorrhages the prothrombin time was less than 40% and in the fourth 75%. In each case, vitamin K_1 had been administered, with transient restoration of the prothrombin time to above 60%. It is felt, in retrospect, that the elevation of the prothrombin time prior to operation created a false sense of security. It appears that when there is a significant depression of the prothrombin time, serious consideration must be given to the risk of hemorrhage and, if the biopsy is performed, adequate amounts of vitamin K_1 should be given preoperatively and permanent restitution of a normal time assured. Preferably, administration of vitamin K_1 should be continued postoperatively until all danger of hemorrhage has passed. Attention to prothrombin consumption time is also important, since it may be dangerously low even in the presence of relatively normal prothrombin activity.

One patient in whom the above precautions were carried out continued to bleed in spite of repeated transfusions and administration of vitamin K_1. Biopsy reveale chronic myelogenous leukemia. The prothrombin consumption time was found to be 20%. The hemorrhag was halted abruptly with the transfusion of 500 cc. o fresh whole blood. This experience suggests that whe a blood dyscrasia is suspected, even in the face of norm bleeding, clotting, and prothrombin times, a prothromb consumption time should be determined prior to oper tion in order to reduce the risk of hemorrhage. It wou probably be wise to utilize this test also in cases of di fuse hepatic disease.

The liver biopsies in this study were performed, whe ever possible, by the abdominal approach; however, 19 cases the transthoracic route was required. It is i teresting to note that two of the patients with hem rhage, including the one who died, had transthora biopsies. There was a 10.5% incidence of hemorrha in the transthoracic group, as opposed to an incidence of 1.7% in the abdominal group. The frequency of transient pain localized to the site of transthoracic puncture was twice that encountered with the abdominal approach, the incidences being 21.1% and 10.0% respectively.

[2] Zamcheck, N., and Klausenstock, O.: Medical Progress: Liver Biopsy: II. The Risk of Needle Biopsy, New England J. Med. 249:1062-1069, 1952.

These findings strongly implicate the transthoracic approach as a significant factor in the incidence of operative and postoperative complications. This might well be anticipated in view of the proximity of the intercostal vessels and the lung tissues, the dependence upon the patient's ability to control his respiratory movements during the procedure, and the danger of laceration of diaphragmatic vessels. This approach should be reserved, therefore, for those cases in which the abdominal approach is impossible and in which the diagnostic worth of the biopsy outweighs the risk. The advantage of this mode of approach over that of exploratory laparotomy should be carefully considered.

SUMMARY

In a total of 139 needle biopsies of the liver in 119 patients, 120 were performed by the abdominal approach and 19 by the transthoracic. In 86.2% of the biopsies the diagnosis was accurate. Portal cirrhosis was missed in 4.6% of the total and carcinomas in 45.2%. The mortality rate was 0.72% (one case). Postbiopsy hemorrhage occurred in four cases, including the fatal one, an incidence of 2.9%. Transient localized pain occurred in 16 patients, an incidence of 11.5%. Low prothrombin times were implicated in three of the four cases of hemorrhage, and its correction before and after biopsy is very important. A low prothrombin consumption time was the only abnormality in the clotting mechanism of a patient with chronic myelogenous leukemia who bled postoperatively. It should be determined whenever a blood dyscrasia is suspected. The transthoracic route is a significant factor in the incidence of complications.

VISUALIZATION OF BILIARY DUCTS BY INTRAVENOUS INJECTION OF NEW CONTRAST MEDIUM

Alexander J. Link, M.D., Raj K. Parida, M.B., Julius Heydemann, M.D.
and
Robert M. Kark, M.D., Chicago

Although cholecystography was introduced by Graham and Cole in 1924,[1] until recently there was no simple method of making roentgenologic studies of the bile ducts. Radiopaque materials had to be injected directly into the common duct during or after operation,[2] or they were introduced percutaneously under peritoneoscopic visualization.[3] The necessity of a method that will give good visualization of the gallbladder and bile ducts without surgery can be well appreciated. Recently such studies have been reported from Germany,[4] in which an iodine-containing substance that is actively excreted by liver cells when injected intravenously is used. The high iodine content of the substance makes it possible to visualize the bile ducts early after injection and the gallbladder later. The concentrating power of the gallbladder is not necessary for visualization as it is with other materials. The German workers [5] have reported that, in the absence of parenchymal liver disease, 90% of the substance is removed from the blood stream by the liver and excreted with bile, the remainder being excreted by the kidney. No absorption takes place from the gastrointestinal tract. The iodine is stated to be firmly bound to the molecule, and apparently the dye is excreted in feces or urine without degradation; however, this has to be proved—perhaps by using dye tagged with radioactive iodine. The high molecular weight [6] of the compound may contribute to its selective excretion by the liver.

This paper reports studies made on 21 patients, with and without hepatobiliary disease, who were x-rayed after injection of sodium iodipamide (Cholografin). This radiopaque solution is the disodium salt of N,N′-adipylbis(3 amino-2,4,6-triiodobenzoic acid), and, through its use, satisfactory visualization of the hepatic, cystic, and common bile ducts, as well as the gallbladder, was obtained. Patients were selected for study on the basis of history, physical findings, and tests of liver function. Three patients who were free of hepatobiliary disease were chosen to serve as controls. The remaining 18 were selected because of suspicion that they might have abnormalities of the biliary duct system.

MATERIAL AND METHODS

Sodium iodipamide at present is supplied in 20 cc. ampuls of a 20% aqueous isotonic solution containing 4 gm. of the active agent. In rats, the LD_{50} is 3.4 gm. for sodium iodipamide, while for the preparation for oral use, iodo-

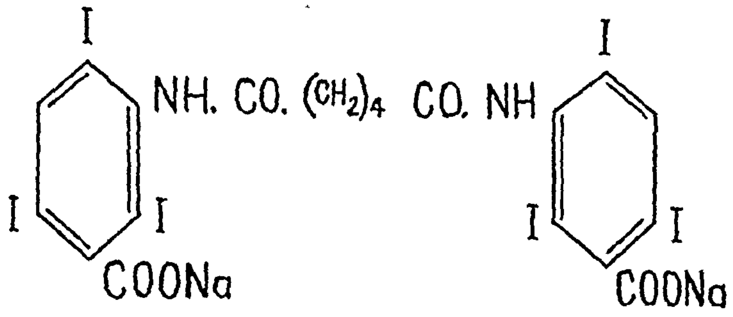
panoic acid (Telepaque), the LD_{50} is 0.36 gm. when given intravenously.[4a] The formula for iodopanoic acid is 3-(3-amino-2,4,6-triiodophenyl)-2-ethylpropanoic acid. In pure form, sodium iodipamide is a crystalline substance. The molecular weight is 1183.35, and the compound contains 64.32% iodine. Its structural formula is:



The tests of liver function included one minute and total bilirubin, serum cholinesterase levels, measurement of gamma globulin, and a number of flocculation tests, including the cephalin flocculation and zinc and thymol turbidity tests. These were done by standard techniques or modifications thereof that have been reported previously.[7] Serial follow-up studies of liver function were also made to determine if the dye had any effects on liver function. The control tests were made in the morning before the dye was injected. A second series of tests was made 48 hours after injection, and the third was done one week later. Patients whose tests were found to be abnormal before injection of the contrast medium were studied on a fourth occasion, one month after injection.

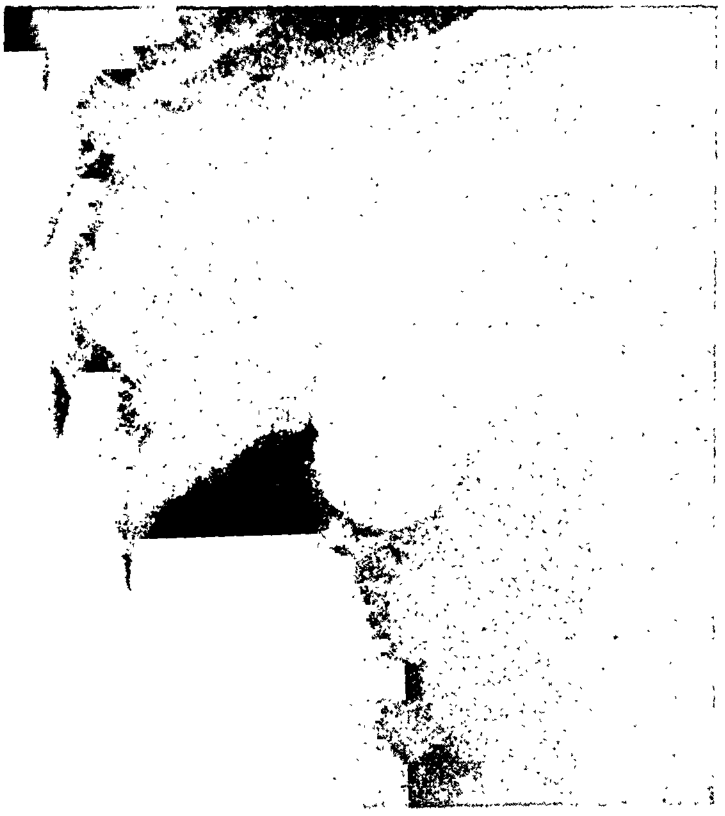


Fig. 1.—O. McN. Normal gallbladder and ducts one hour after injection of one of control patients.

In preparation for the study, the patient was given a cleansing enema the night before, and all oral intake was suspended after midnight. A preliminary posterior-anterior film of the right upper quadrant of the abdomen was taken before injection of the dye. A dose of 1 cc. of the solution was given intravenously as a test for hypersensitivity, although the conjunctival test may suffice.[8] After 5 minutes, 40 cc. of the solution was injected slowly; this usually took 8 to 10 minutes.

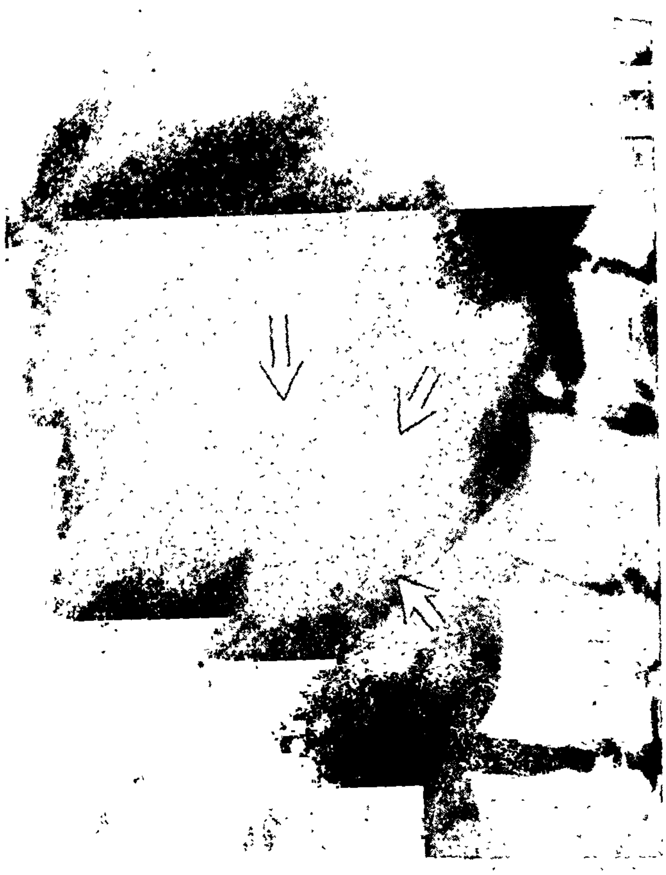

Fig. 2.—H. G. Stones in gallbladder of one of patients with cholelithiasis. Neck of gallbladder filled; cystic and common duct normal.

Roentgenograms were taken immediately, 10 minutes, 20 minutes, 30 minutes, and one hour after the required amount of the solution was injected. Two views, posterior-anterior and left anterior oblique of the right upper quadrant, were taken. A right posterior oblique was substituted if the left anterior oblique film did not prove satisfactory. The films taken immediately after injection have now been eliminated, as not enough material was excreted by the liver to visualize the ducts. For an ordinary cholecystogram 20 cc. is reported to be sufficient for visualization of the gallbladder within two hours after injection. For duct visualization 40 cc. is used. These studies have been confined to visualization of the ducts only.

RESULTS

No serious reactions during or after the injection of the solution were encountered. One-half of the patients experienced no symptoms, the rest stated that they had noticed a peculiar smell, metallic taste, sensation of warmth, pain in the arm and shoulder during injection, or dizziness. Two patients experienced slight nausea. It appears that the development of reactions was a function of the rate of the injection. All the side-effects were transitory. This is in keeping with the previous studies.[9]

9. Frommhold.[4a] Gaebel and Teschendorf.[4b] Hornykiewytsch and Stender.[4c] Pahl.[6]

The data on the three control patients are shown in table 1. Table 2 summarizes findings in five patients with gallbladder symptoms who were not operated on before the examination. Table 3 summarizes findings in 13 patients who had the so-called postcholecystectomy syndrome. In the control group of three patients (table 1 and fig. 1), good visualization of the ducts was obtained within 10 to 30 minutes after the solution was injected. The gallbladder was visualized in one-half hour to two hours; occasionally visualization of the urinary collecting system occurred within 20 to 30 minutes. When this happened, oblique films were necessary to separate overlapping structures. Of five patients (table 2) who had signs and symptoms of hepatobiliary disease but who did not have previous gallbladder or common duct surgery, visualization of the ducts was obtained in four. In the patient with biliary cirrhosis the ducts did not fill (E. M.). In two patients (H. G. and M. S., fig. 2) with cholelithiasis, the ducts filled well and were normal in size. In the patient (D. B.) who had vague generalized pain without any definite gallbladder symptoms, the ducts filled well but appeared slightly dilated. The presumptive clinical diagnosis was a tumor causing a partial obstruction of the bile ducts.

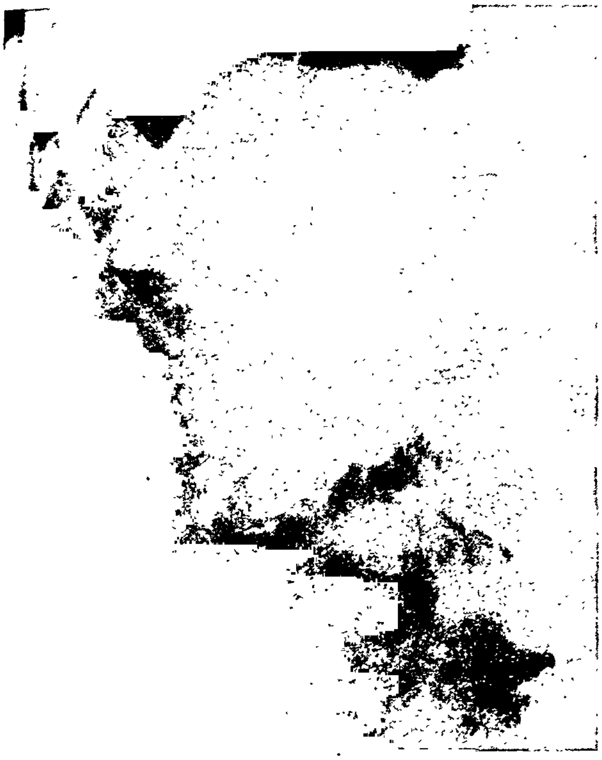

Fig. 3.—D. D. Cholecystectomy 13 years ago. Choledochoenterostomy 12 years ago. Persistent pain, intermittent jaundice. X-ray shows stricture of hepatic duct.

In 13 patients with postcholecystectomy symptoms (table 3) 5 patients were found with poor visualization to nonvisualization of the ducts and 8 with good visualization. Stricture of the common duct was diagnosed in one patient (D. D., fig. 3) preoperatively and was subsequently confirmed at operation. In two patients (T. R. and N. C.) the diagnosis of recurrent pancreatitis was made after this study ruled out any stricture or stone in the biliary ducts. In one of these patients (N. C., fig. 4) the ducts were dilated without any demonstrable cause. In one patient cholangiography was done on two occasions; once before cholecystectomy and common duct exploration and, as the patient continued to have pain and abnormal liver function test, two months after surgery. Good visualization of the ducts was obtained on both occasions, and the patient was discharged from the hospital without additional surgery. The remaining four patients had recurrent attacks of abdominal pain following cholecystectomy. Good visualization of the ducts was obtained, and the pain could not be attributed to common duct pathology.

Some or all of the liver function tests were abnormal in 11 patients in this series (tables 1, 2, and 3). In some, however, only the flocculation tests and gamma globulin levels were abnormal, which can very well be caused by conditions other than liver damage.[10] In only one patient (E. G.) was any significant deterioration of tests of liver function detected that may be ascribed to the injection of sodium iodipamide. In 6 of 11 patients good visualization of the biliary ducts was obtained.

COMMENT

The study of the bile ducts of such a small group of patients does not warrant any conclusions. When the results of these studies were compared with those of the German workers [9] who have made extensive studies with this substance, several of their observations were confirmed. First, the contrast medium did not produce any serious ill-effects; liver function was not disturbed; and

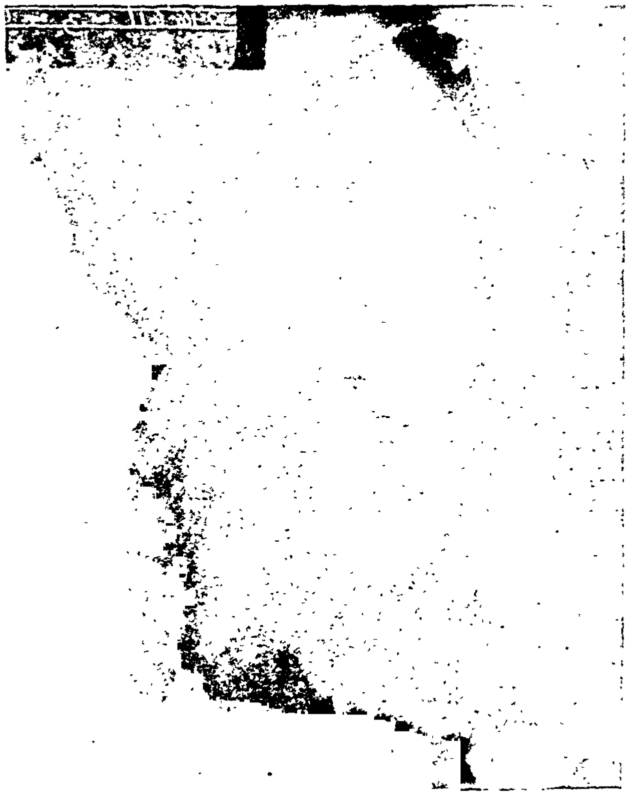

Fig. 4.—N. C. "Postcholecystectomy syndrome." Dilated but patent common duct. Diagnosis: chronic pancreatitis.

---

[10] Hanger, F. M.: The Meaning of Liver Function Tests, Am. J. Med. 16: 565, 1954.

reactions, thus far, have been mild and not disturbing. Second, x-ray visualization of the ducts was not obtained in six patients. Two of these had free air in the bile ducts due to previous surgery but showed normal liver function; the other four had abnormal liver function, with or without clinical evidence of intermittent jaundice, cirrhosis, or a draining T tube in the common duct. In one patient with an elevated bilirubin level the ducts were poorly visualized. It is disappointing to find poor visualization or nonvisualization of the ducts in 6 out of the 21 patients studied, but it is reasonable to expect that with improvement in techniques the percentage of adequate visualization will be raised, if serious liver damage is absent. The common and terminal portions of the right and left hepatic ducts were well visualized in 15 patients, but the smaller intrahepatic ducts were not visualized except in one patient of the control group. If the small hepatic ducts could be visualized, the value of the examination would be enhanced for the possible diagnosis of intrahepatic abscesses and primary and secondary liver tumors.

From the studies, it is believed that the indications for the examination are: (1) complaints following cholecystectomy, (2) suspected common duct stone, (3) normal cholecystogram by other methods but persistent symptoms, (4) inability to take or intolerance to oral preparations, and (5) need for rapid diagnosis. Although the examination is time consuming and must be made under the constant supervision of a physician, sodium iodipamide now has a place in the roentgenologic study of the pathology of the biliary ducts. For the time being, the use of this compound is not advisable in patients who have severe liver disease, sensitivity to iodine, or toxic diffuse goiter (Graves' disease). This study shows, however, that the procedure is safe and can be done on nonhospitalized patients. The results of these studies with sodium iodipamide appear encouraging; the preparation is useful and should be given further trial in a large number of cases.

SUMMARY

Sodium iodipamide (Cholografin), the disodium salt of N,N'-adipyl-bis (3 amino-2,4,6-triiodobenzoic acid), a new roentgenologic contrast medium, was used to study the biliary duct system in 21 patients. Adequate roentgenologic visualization of the large bile ducts was obtained in 15 of the 21 patients after intravenous injection of the material. The six patients with nonvisualization of the ducts had either severe hepatic dysfunction or air in the ducts due to previous surgery. No serious reactions developed following slow injection of the compound. The low toxicity of the compound was confirmed by means of serial tests of liver function, which did not change after injection of the preparation. The preparation appears to be a useful adjunct for the diagnosis of biliary diseases and especially for intraductal pathology.

OCCULT CARCINOMA OF THE PROSTATE

CLINICAL AND THERAPEUTIC STUDY OF EIGHTY-THREE CASES

Laurence F. Greene, M.D.
and
Howard B. Simon, M.D., Rochester, Minn.

At times the urologist is surprised to learn that a prostate gland with enlargement that he had considered to be benign is found to be carcinomatous by histological study following prostatectomy. The therapeutic problem thus presented is one concerning which a divergence of opinion exists. One school of thought suggests that radical perineal prostatectomy should be performed in such cases, whereas the other believes that the conservative prostatectomy already performed, the one by which the diagnosis of occult carcinoma was established, is sufficient. Thus Brendler stated that "it becomes mandatory at this time, and until convincing evidence to the contrary be submitted, that the patient with occult prostatic cancer be given the benefit of radical prostatectomy, providing, of course, that he be a suitable candidate from the standpoint of physical condition and life expectancy."[1] The Hinmans supported this contention and cited results in five patients so treated and followed for more than five years.[2] An average survival period of 68 months was noted in these patients, in contrast to an average survival period of 37 months in nine patients treated by prostatic resection alone. A similar opinion has been expressed by Goodwin[3] and Harrison and Poutasse.[4]

Nesbit and Baum,[5] on the other hand, stated: "Are we justified in subjecting patients with occult prostatic cancer to the operative risk and the morbidity often attendant on radical perineal prostatectomy in the light o present available survival statistics? . . . The results o conservative management offer a challenge which th advocates of radical prostatic surgery must at least mee

and preferably improve upon before the urologist can advise such a procedure for the treatment of unsuspected prostatic malignancy." These authors reported their study of 42 patients with occult prostatic carcinoma. They noted that 26 patients were living without evidence of recurrence, 65% of whom had been followed three years or longer, while 2 patients had died of prostatic cancer and 14 had died of other causes. They concluded, therefore, that conservative management is indicated in the treatment of occult prostatic carcinoma. Similarly, Labess[6] reported that of 33 patients with occult carcinoma treated by suprapubic enucleation and followed for more than five years, 26 (85%) survived five years or more.

INCIDENCE

Reports concerning the clinical incidence of occult carcinoma of the prostate are few. Young[7] reported the incidence of carcinoma to be nearly 11% in 4,295 prostates removed surgically; of these carcinomas, 76 or 16% were unsuspected prior to operation. Smith and Woodruff[8] found occult carcinoma in 62 of 648 cases of carcinoma of the prostate, an incidence of approximately 9%.

PURPOSE OF PRESENT STUDY

The purpose of this study was to determine the course of patients with occult prostatic carcinoma treated by transurethral resection; adjuvant forms of therapy, as will be described later, also were employed. The cases of occult carcinoma of the prostate that comprise this study satisfied the following criteria: 1. Each patient was examined by urologic and medical consultants, and in each instance the prostatic enlargement, noted by digital-rectal examination, was considered to be benign. 2. Metastatic malignancy was not suspected in preoperative roentgenograms. 3. A suspicion of malignancy was not raised during the course of transurethral prostatic resection. Thus, the presence of malignancy was unsuspected in each case prior to receipt of the pathologist's report. Clinical records of 2,090 patients with prostatic carcinoma treated during the 15 year period of 1934 to 1947 inclusive were studied, and 83 cases fulfilled the criteria mentioned above.

AGE DISTRIBUTION OF PATIENTS AND SIZE OF PROSTATE

The age distribution of the patients is shown below. The average age of the group was 68 years; the youngest patient was 51 years of age and the oldest 84. The great majority of patients (about 85%) were in the seventh and eighth decades of life at the time of diagnosis. The estimates of the size of the prostates, as determined by digital-rectal palpation and graded on the basis of 1 to 4, were: grade 1, 28 patients (33.7%); grade 2, 42 patients (50.6%); and grade 3, 13 patients (15.7%). None of the 83 patients had prostates of a size to be classified as grade 4. The actual weight of prostatic tissue removed varied from 6 to 141 gm., the average being 22 gm. The weight distribution is shown below.

Age, Yr.	Patients	
	No.	%
50-59	7	8.4
60-69	39	47.0
70-79	32	38.6
80-89	5	6.0
Total	83	100.0

Weight, Gm.	Patients	
	No.	%
0-19	39	47.0
20-39	23	27.7
40-59	14	16.9
60-79	6	7.2
80 +	1	1.2
Total	83	100.0

X-RAY AND LABORATORY FINDINGS

Preoperative plain roentgenograms of the urinary tract were made in 77 of the 83 cases, and roentgenograms of the chest were secured in all cases. In each case the roentgenogram was negative for evidence of metastatic bone lesions. Inasmuch as prostatic malignancy was not suspected, preoperative determinations of serum phosphatase were not made; however, determinations of acid and alkaline serum phosphatase were made during the immediate postoperative period in 15 cases, and in each case the values were normal.

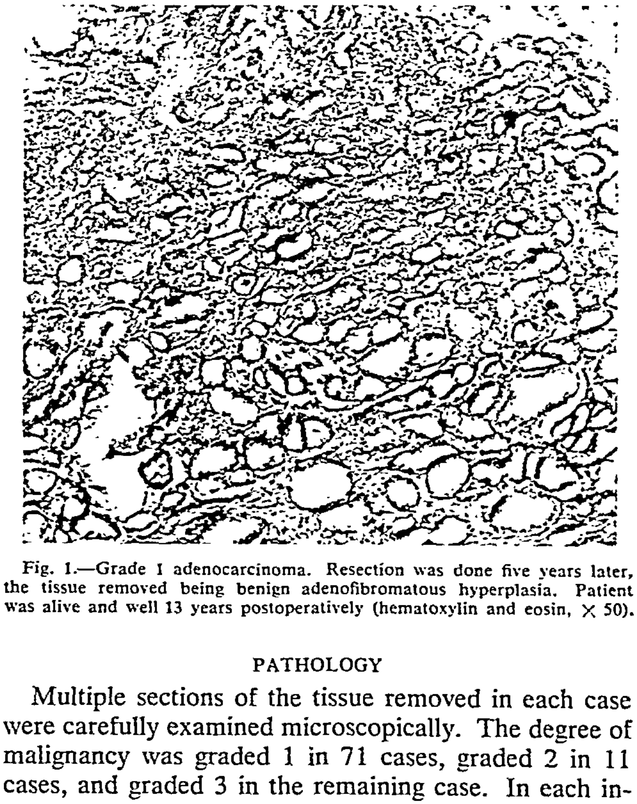

Fig. 1.—Grade I adenocarcinoma. Resection was done five years later, the tissue removed being benign adenofibromatous hyperplasia. Patient was alive and well 13 years postoperatively (hematoxylin and eosin, × 50).

PATHOLOGY

Multiple sections of the tissue removed in each case were carefully examined microscopically. The degree of malignancy was graded 1 in 71 cases, graded 2 in 11 cases, and graded 3 in the remaining case. In each instance the neoplasm was considered to be adenocarcinoma (fig. 1, 2, and 3). The diagnosis of adenocarcinoma of the prostate, grade 1, is sometimes considered a diagnosis of equivocation; however, fulfillment of the following three criteria would seem to permit of an unequivocal diagnosis[9]: 1. The prostatic acinus acquires a small lumen. 2. The lining epithelium loses its papillary infoldings. 3. Lipid appears in the cytoplasm. Support for this viewpoint is gained from the studies of Kahler, who noted perineural lymphatic involvement in 87% of the cases of adenocarcinoma, grade 1. Evidence of metastasis was noted in 51% of such cases recognized grossly at autopsy.

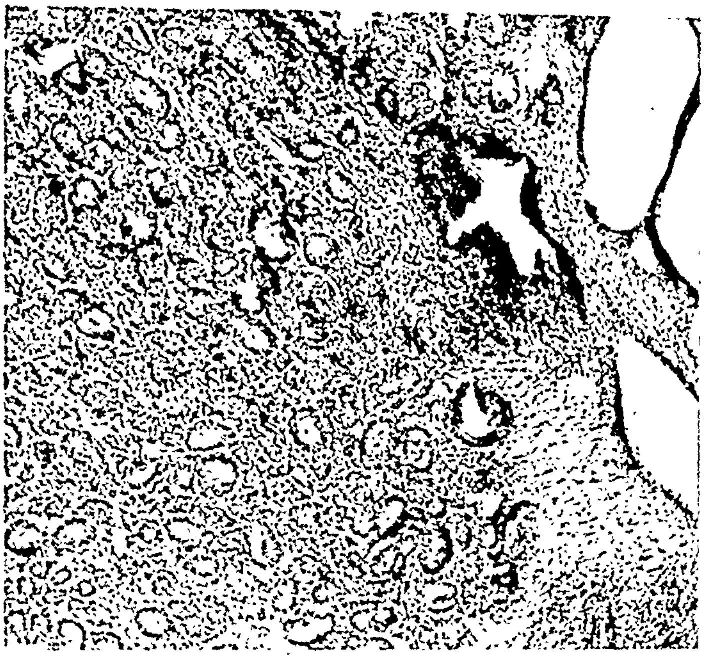

Fig. 2.—Grade 1 adenocarcinoma. Patient had no evidence of recurrence or metastasis at follow-up examination 7 years after the operation and was alive and well 11 years postoperatively (hematoxylin and eosin, × 50).

Certain changes in prostatic epithelium may be confused with adenocarcinoma. One of these changes is metaplasia, or squamatization, of the prostate. In this condition, the epithelium of the prostate gland becomes hyperplastic in the process of repair of damaged ducts and acini around an infarct or at the edge of the necrosis following transurethral prostatic resection. This hyperplastic epithelium has, in the past, been confused with carcinoma, but it is recognized readily in that frequently the islands of epithelium do not have a lumen, or, if they do have a lumen, there is an absence of fat in the cytoplasm. We believe that the histological diagnosis of adenocarcinoma, grade 1, if applied conservatively, is subject to little error. Some of the carcinomas in this series were microscopic in size, and most of the lesions were found in association with adenofibromatous hyperplasia; the latter finding is in accord with those of Rich[10] and Andrews.[11]

TREATMENT AND RESULTS

The forms of therapy employed in these 83 patients were: transurethral resection and diethylstilbestrol, 43 patients; transurethral resection, 37; transurethral resection and orchiectomy, one; transurethral resection and roentgen therapy, one; and transurethral resection, diethylstilbestrol, and roentgen therapy, one. It will be noted that transurethral resection and administration of diethylstilbestrol were employed in 43 cases. In this group, diethylstilbestrol therapy was instituted during the postoperative period in 39 instances, while the remaining four patients did not receive hormonal therapy until two to seven years later. The patient who underwent orchiectomy did so four years after prostatic resection. One patient, given roentgen therapy during the postoperative period, received diethylstilbestrol nine years later. Thus, the majority of patients were treated either by transurethral resection alone or by resection supplemented with diethylstilbestrol therapy.

Observed Survival Rates Compared with Expected Survival Rates (Normal Population)

		Lived Beyond Indicated Period		
Period, Yr.	Patients	No.	Survival Rate, % †	Expected Survival Rate for Normal Population Aged 68 to 69, % *
5	82	58	70.7	75.4
10	33	13	39.4	48.7

* United States Life Tables (white males, 1940).[12]

† Inquiry as of Jan. 1, 1953. The 5 yr. group includes those patients operated on in 1947 or earlier; the 10 yr. group includes those operated on in 1942 or earlier.

Survival Rate.—It was possible to reexamine or correspond with 82 of the 83 patients who comprised our study; this permitted us to collect data concerning survival for 82 patients followed 5 years or more and 33 patients followed 10 years or more. The 5-year and 10-year survival rates are shown in the table. This table also includes the expected survival rates for the normal population at age 68 to 69 years[12] (the average age of the patients included in our study). It will be noted that the survival rates for our patients compare favorably with survival rates for the normal population. This comparison tends to emphasize the relatively low order of malignancy of occult prostatic carcinoma.

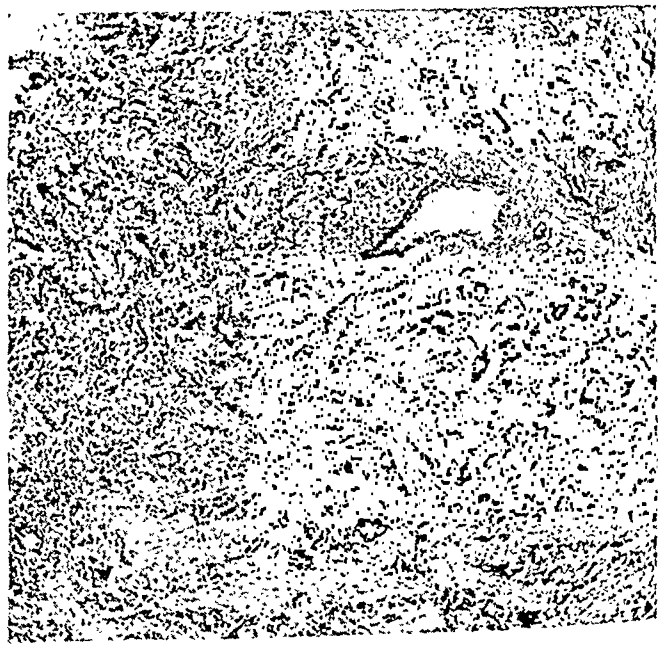

Fig. 3.—Grade 3 adenocarcinoma. Patient died three years postoperatively, at age of 74, but with no evidence of recurrence prior to death (hematoxylin and eosin, × 50).

State of Health and Cause of Death.—In addition to determining the number of years the patients survived, we sought to determine the state of their health during these years and, if possible, the cause of death. We wished to learn whether the patients survived comfortably or whether they suffered from prostatic carcinoma. We believe we have valid information in this respect concerning 67 of the 82 patients in the study. This information was obtained partly by examinations conducted at the time of return visits of the patients to the clinic and partly by questionnaires. The difficulty of adequate appraisal by means of questionnaires is acknowledged, but we believe that the specificity of our questions and the nature of the responses permit valid deductions concerning the state of health and causes of death of 67 patients.

[12] Life Table for Total Males in the United States: 1939-1941, in Greville, T. N. E.: Sixteenth Census of the United States: 1940, United States Life Tables and Actuarial Tables, 1939-1941, U. S. Department of Commerce, Bureau of the Census, 1946, pp. 28-29.

Fifty-five of these 67 patients (82%) did not experience further symptoms that we considered to be due to prostatic carcinoma, and the cause of death of those patients deceased at the time of this study (22 patients) was not considered to be prostatic carcinoma. The following information pertains to these 55 patients. Twenty-five patients were reexamined at the clinic on subsequent occasions and prostatic malignancy, local or metastatic, was not detected. Six patients underwent a second transurethral prostatic resection or suprapubic prostatectomy because of recurrent urinary obstructive symptoms one to eight years after the initial resection; in each instance, microscopic examination of the tissue removed failed to disclose carcinoma. Forty-two patients survived five years or more. A 10-year follow-up was possible for 19 patients, and 9 lived 10 years or more. Twelve of the 67 patients suffered ill health and recurrent urinary obstructive symptoms, and it is highly probable that death of the patients deceased at the time of this study (7 patients) was due to prostatic carcinoma. The following information pertains to these 12 patients. Seven patients returned to the clinic for reexamination, and a diagnosis of local or metastatic carcinoma of the prostate was made. Whether the recurrent urinary obstructive symptoms suffered by the remaining five patients were attributable to prostatic carcinoma can only be conjectured inasmuch as they did not return for reexamination. It is possible that the recurrent prostatism was due to regrowth or residual benign prostatic tissue. Ten patients survived five years or more. A 10-year follow-up was possible for eight patients, and four lived 10 years or more.

Thus, from the standpoint of health and well-being, 55 of 67 patients (82%) enjoyed good health postoperatively and did not experience symptoms that could be attributed to prostatic malignancy. Furthermore, the cause of death of the patients in this group who were deceased at the time of this study was not prostatic malignancy. Finally, the longevity of those patients who continued to experience symptoms that were definitely or possibly related to prostatic malignancy was appreciable. These data likewise suggest the relatively low order of malignancy of occult prostatic carcinoma.

Effect of Postoperative Therapy with Diethylstilbestrol on Survival.—Survival data on patients treated by resection alone (37 patients) were compared with similar data on patients treated by resection and immediate diethylstilbestrol therapy (39 patients). Comparative data suggest that diethylstilbestrol therapy, instituted during the postoperative period, neither increases survival nor decreases morbidity. Thus, 73% of patients treated by resection alone survived five years, whereas 67% of patients treated by resection and diethylstilbestrol survived five years. (The number of patients in these groups followed 10 years or more is too small for statistical studies.) In view of the slight degree of anaplasia of the carcinomas in this study, such results from hormonal therapy are to be expected.

COMMENT

This study was undertaken to give information concerning the prognosis, in respect to both survival and morbidity, for patients with occult prostatic carcinoma. Our data indicate that survival rates for such patients treated by transurethral resection (alone or with diethylstilbestrol) closely approach normal survival rates. The table indicates that expectancy for 5 year survival is about 95% of normal and expectancy for 10 year survival is about 85% of normal. The prognosis concerning morbidity is equally encouraging. At the time this study was made, approximately 80% of the patients remained free of symptoms that could be attributed to carcinoma; the cause of death of the deceased patients was not prostatic carcinoma. Approximately 10% of patients had recurrent urinary obstructive symptoms. Our information was not sufficient to determine whether this was the result of prostatic carcinoma, secondary to an inadequate resection, or due to recurrence of benign prostatic hyperplasia. Finally about 10% of patients subsequently had symptoms and findings of prostatic carcinoma, and it is highly probable that death of the patients deceased at the time of this study was the result of prostatic carcinoma.

The fact that 10 to 20% of patients developed symptoms that were definitely or possibly the result of prostatic carcinoma might be considered an indication that transurethral resection is inadequate therapy. It cannot be denied that some of these patients might have been cured if radical prostatectomy had been performed. Unfortunately, we know of no criteria that will indicate which patients with occult carcinoma require radical prostatectomy. It should be pointed out, however, that survival of patients in our series whose clinical course was not satisfactory (20%) was, nevertheless, appreciable. Thus, in this group, the average survival of the patients deceased at the time of our study was six years, while those patients still living had survived an average of eight years.

It is our opinion that three factors are largely responsible for the good prognosis for patients with occult prostatic carcinoma. These are grade (Broders' method), size, and biological potential of the carcinoma. It will be noted that with but one exception all the carcinomas in this study were low grade, that is, grade 1 or 2 (graded on the basis of 1 to 4, in which grade 1 is the least malignant and grade 4 the most malignant). Indeed, 85% of the carcinomas in this series were graded 1. Thompson[13] has already established a direct correlation between the grade of carcinoma and prognosis and has pointed out that 60% of patients with carcinoma, grade 1, irrespective of the size or extent of the lesion, survive five years or more.

---

[13] Thompson, G. J.: Carcinoma of the Prostate, Urologists' Correspondence Club, April 15, 1954.

In many instances in our series, the carcinoma was microscopic in size, and it is possible that it was excised completely by transurethral resection. Thus, it was not unusual for the pathologist to report the presence of a microscopic area of carcinoma in one section of tissue and its absence in numerous other sections that were made for the express purpose of detecting carcinoma. The records of six patients indicate that the carcinoma may be excised completely by transurethral resection. These patients underwent resection and a diagnosis of occult prostatic carcinoma was established; a subsequent resection or suprapubic prostatectomy performed one to eight years later because of recurrent urinary obstruction failed to disclose carcinoma. Complete excision of carcinoma by conservative prostatectomy has been reported by Goodwin,[3] Hinman,[2] and Jewett.[14] Goodwin reported that radical prostatectomy was performed in 14 cases after a diagnosis of carcinoma had been established by simple perineal, suprapubic, retropubic, or transurethral prostatectomy. In five of these cases, residual carcinoma could not be detected.

Finally, our study indicates that the biological potential of occult prostatic carcinoma may be of lower magnitude than those carcinomas that can be detected by rectal palpation. It is possible that occult carcinoma originates in periurethral glands.[15] Certainly there is no reason why the periurethral glandular epithelium should be immune to malignant change, and such an hypothesis would explain the apparent complete removal of malignancy by simple prostatectomy cited previously. Kahler has pointed out that carcinoma originates at a site other than the posterior lamella in 54% of cases. It is conceivable that carcinoma arising from periurethral glands or prostatic sites other than the posterior lamella are associated with a pattern or rate of cellular activity different from those that originate in the posterior lamella of the prostate gland and that are commonly recognized by digital-rectal examination.

SUMMARY AND CONCLUSIONS

The records of slightly more than 2,000 cases of carcinoma of the prostate gland were reviewed, and 83 cases of occult carcinoma were found in which the treatment consisted of transurethral prostatic resection. The expectancy for 5 year and 10 year survival was approximately 95 and 85% of normal respectively. Some 80% of patients remained free of symptoms that could be attributed to prostatic carcinoma. The favorable prognosis in respect to survival and morbidity is attributed to: (1) low grade of the carcinoma, (2) small size of the carcinoma, with the possibility in some cases of its total removal by resection, and (3) lower magnitude of malignancy of occult carcinoma related possibly to its origin in periurethral glands. Diethylstilbestrol therapy does not influence the prognosis favorably. Finally, in view of the statistics presented, the advisability of radical prostatectomy after prostatic resection has disclosed occult carcinoma is questioned.

FEMORAL ARTERIOGRAPHY IN DIAGNOSIS OF SEGMENTAL ARTERIOSCLEROSIS OBLITERANS

Charles M. Greenwald, M.D., Fay A. LeFevre, M.D., Joseph C. Root, M.D
and
Alfred W. Humphries, M.D., Cleveland

Femoral arteriography has taken on new diagnostic importance with the advent of the use of arterial implantations in the treatment of selected cases of segmental arteriosclerosis obliterans. Although the history and physical examination alone will disclose the presence of peripheral vascular disease, these must be supplemented by arteriography to disclose the special condition of segmental occlusion. The frequency of segmental occlusion in arteriosclerosis obliterans makes arteriography an indispensable component of the clinical evaluation of the disease. The purpose of this paper is to describe a technique of femoral arteriography that has provided uniformly good results, to summarize the findings of 103 consecutive femoral arteriograms of 76 patients, and to correlate these findings with certain clinical data and prognoses.

TECHNIQUE

The technique of arteriography now employed at the Cleveland Clinic has evolved from three main objectives: (1) safety to the patient, (2) continuous visualization of the arterial tree, and (3) simplicity of equipment. Perhaps the most important single departure from the usual technique is injection by means of arterial catheterization. In the past, femoral catheterization primarily was used for retrograde aortography. Farinas [1] was a pioneer in this field, using a rubber ureteral catheter, which he inserted through a trocar. More recently, Peirce [2] employed polyethylene tubing.

Arteriographic examination is performed in the operating room. After cleansing of the femoral triangle area, a 14 gauge needle is directed proximally into the femoral artery (fig. 1). The obturator is removed, and

[2] Peirce, E. C., II: Percutaneous Femoral Artery Catheterization in Man with Special Reference to Aortography, Surg., Gynec. & Obst. **93**: 56, 1951.

a plastic catheter is inserted through the needle until the tube extends into the common femoral artery for a distance of 2 to 3 in. (5 to 8 cm.). The needle is then withdrawn over the catheter. Injection by catheter possesses several advantages: It minimizes local trauma, minimizes the danger of extravasation, and minimizes the danger of exposure. The sharp-pointed needle does not remain in the lumen, where it can come in contact with the vessel wall. Movement of the needle, particularly during forceful injection, has been considered a prime source of local trauma. The catheter is threaded well into the artery, thus minimizing the danger of extravasation that results from incorrect placement of the needle. The added length of the catheter allows a greater distance between the hand of the injector with the syringe and the roentgen ray field, thus minimizing the exposure. A check with a dosimeter in our cases revealed an average exposure of only 20 milliroentgens to the hand of the injector. This catheter technique almost completely eliminates the major local complications of hemorrhage, extravasation, and local trauma and allows for percutaneous injection with relative safety.

Initially, iodopyracet (Diodrast) was used as the contrast medium, but at present, sodium acetrizoate (Urokon) is preferred. Twenty-five cubic centimeters of 50% sodium acetrizoate is used. This solution is considered to be the maximum safe concentration for peripheral arteriography. (We agree with Lindbom [3] that only in the aorta can 70% sodium acetrizoate be tolerated.) To allow for filling of the collaterals, the operator slowly injects the first 15 cc. during a 10 second period. The remaining 10 cc. is given as rapidly as possible, and the arteriogram usually is obtained simultaneously with the completion of injection. Exposure may be delayed in certain instances, as in the study of vascular malformations to obtain a venous phase. We keep the equipment simple by omitting the use of a pressure control injection apparatus, which we believe is unnecessary.

Catheter in place, needle removed
Syringe to catheter in femoral artery

Fig. 1.—Technique of injection of contrast medium by catheter.

The only special piece of apparatus that is required is a 14 by 36 in. cassette with maximum speed screens.

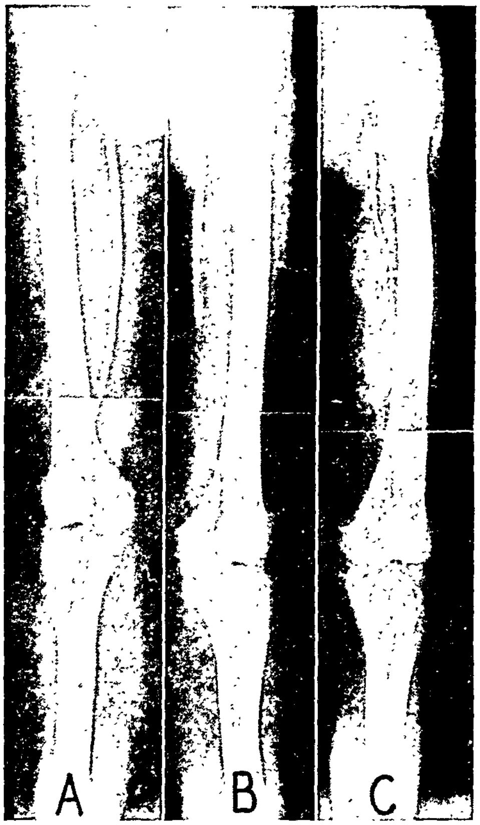

Fig. 2.—Arteriographs (*A, B*) of a 57-year-old man with arteriosclerosis obliterans with bilateral intermittent claudication and (*C*) of a 73-year-old man with arteriosclerosis obliterans with claudication, rest pain, and a small ischemic ulcer. *A*, local intimal disease of the lower superficial femoral artery of the right limb. *B*, short segmental occlusion of the superficial femoral artery of the left limb, with good refilling distally. A symmetrical tendency is apparent, the arterial tree being free of disease except for the region of Hunter's canal. *C*, occlusion of the superficial femoral artery of the left limb from its bifurcation, without refilling. Collateral circulation is inadequate, and multiple small vessels from the profunda extend below the knee.

The use of a single 14 by 36 in. roentgen ray film requiring special darkroom handling is unnecessary, since two regular 14 by 17 in. films can be butted together within the special cassette. The two films provide uninterrupted visualization of the arterial tree, both of the upper leg and of the lower leg, which is highly important for proper evaluation of the disease. To facilitate changing of the cassette, a wood and Masonite tunnel is placed under the limb to be examined. It has not been found necessary to use a Bucky frame. A thin sheet of aluminum, 0.041 in. thick, is placed over the cassette in the tunnel to reduce the scattered radiation. A portable unit with a capacity of 100 ma. is used. The tube is raised to a maximum height of 39 in. above the film, is centered over the femoral triangle, and is tilted 10 degrees toward the feet. An aluminum wedge from 0 to 8 mm. in thickness is placed under the tube port to compensate for the

distally diminishing thickness of the limb. The resulting roentgenogram is of fairly uniform density.

For arteriography, the patient is lightly anesthetized with thiopental (Pentothal) sodium supplemented by succinylcholine chloride. The latter drug has a curare-like action obtained by muscle depolarization, which permits the dosage of thiopental to be kept at a minimum. Succinylcholine chloride is administered immediately preceding the injection of the sodium acetrizoate. Without general anesthesia, not only is there pain and discomfort for the patient but the involuntary motion of the patient prevents the obtaining of satisfactory radiograms. While the film is being rapidly developed and inspected, the catheter is left in place. Thus, if the film proves to be unsatisfactory, a repeat study can be performed. After the catheter has been removed, manual pressure is maintained over the area for two to three minutes. With this technique, a total of 129 individual arteriograms has been obtained; there have been no significant complications, and in no case did the procedure appear to aggravate any existing ischemia.

RESULTS

In this series, 103 consecutive femoral arteriograms revealing arteriosclerosis obliterans in a total of 76 patients have been studied. For 27 patients, both extremities were examined, and, for the remaining 49, one extremity was examined. In many of the bilateral studies, the clinical and arteriographic findings were somewhat different in the two limbs. Because of this variation, each arteriogram is separately considered in our report of the findings. A symmetrical tendency was clearly apparent; however, in no case was there a gross discrepancy when bilateral arteriograms were obtained.

The pathological arteriographic findings have been classified into three groups: intimal disease only, occlusion with refilling, and occlusion without refilling. In intimal disease (group 1) there are varying degrees of narrowing of the lumen of the vessel, ranging from minimal irregularity to incomplete block. The continuity of the vessel is maintained, however, and total occlusion does not occur. Collateral circulation usually is scanty, no matter how extensive and diffuse are the intimal changes (fig. 2*A*). In occlusion with refilling (group 2) a segment of the vessel is completely blocked, but there is good collateral circulation that bypasses the defect. Eventually there is filling of the vessel distal to the occlusion (fig. 2*B*). In occlusion without refilling (group 3) there is complete block of the vessel with collateral circulation extending a variable distance below the block. The parent vessel never is refilled. This is the severest form of arterial disease (fig. 2*C*). In the last two groups a varying degree of intimal disease usually is present elsewhere in the arterial tree, but the occlusion is the dominant feature. On the basis of this classification, the findings in our series are analyzed in table 1. The presence or absence of claudication and/or ischemia also were taken into consideration. An ischemic limb indicates, in addition to simple claudication, the presence of rest pain with or without ulceration and gangrene. The level of filling as seen on the arteriogram also is recorded in table 1. The pertinent clinical data are recorded in table 2.

COMMENT

The most important function of femoral arteriography as related to patients having arteriosclerosis obliterans is to identify conditions of segmental occlusion so that they may be surgically corrected. The surgical correction is accomplished by means of arterial implantation or grafting. This procedure is indicated only in certain cases of segmental block with refilling (group 2). In our series of 103 arteriograms, 52 limbs (51%) were classified in group 2. Some of those limbs, however, were not suitable for surgical treatment because of one of the following reasons: 1. The length of the block was too great. 2. Collateral circulation was good so that the only symptom was minimal claudication. 3. Extensive intimal disease was present throughout the vessels. Of the 23 limbs classified in group 3 (occlusion without refilling), in only 6 (9% of 67 cases) was claudication alone present, and in 17 (47% of 36 cases) ischemia was present (table 1). In our experience, good results with arterial grafting are obtained only in those cases in which there is adequate refilling of the vessel distal to the block.

Femoral arteriography not only aids in the selection of cases suitable for surgery but may aid in prognosis as well; for example, arteriography may be of help in determining the advisability of amputation. It is of interest to analyze those cases in which ischemic changes dictated the need for major amputation of the limb at a level proximal to the ankle. The arteriograms of the majority (7) of the 12 limbs that were amputated showed occlusion without refilling (group 3); 4 showed intimal disease alone (group 1); and one showed segmental occlusion with refilling (group 2); the patient classified in group 2 also had diabetes. Seven of the amputations were in men, at an average age of 62 years; and 5 were in women, at an average age of 61 years. An indication of the increased severity of arteriosclerosis obliterans in women is the fact that of the 14 women's limbs in which arteriography was done, 5 (36%) subsequently were amputated; whereas, of the 89 men's limbs in which arteriography was done, only 7 (8%) were amputated. There were only 12 limbs of diabetic patients in the ischemic group of 36 limbs, and yet, 8 of the 12 limbs that were amputated were from diabetic patients; thus, two-thirds of the number of limbs of diabetic patients with clinically severe disease eventually required amputation. This high proportion of diabetic patients requiring radical surgery emphasizes the extraordinary potential danger to the diabetic patient who has any degree of arterial insufficiency.

The typical amputated limb showed a complete block high in the thigh and collaterals that did not reach the popliteal bifurcation. When a deviation from this picture occurred and the arteriographic findings appeared to indicate a milder disease than that which was clinically present, the patient usually had diabetes. Almost without exception, segmental block in the nondiabetic patient is a guarantee against amputation.

The use of the arteriographic findings as a guide to the optimum level of amputation was first described by Veal[4] in 1935. He reported 23 amputations for peripheral vascular disease performed below the knee, of which only 4 later needed revision. Evaluation was based on findings on a single 14 by 17 in. film showing an area that extended from the lower thigh to the midcalf. Many authors[5] consider one of the prime values of femoral arteriography to be its aid in determining the amputation site. In the present series, 8 of the 12 amputations were at the supracondylar level; 4 were performed below the knee. In these four patients, the major indication for the amputation at this site was the arteriographic finding that the level of filling of the vessel extended to the popliteal bifurcation. All four had satisfactory healing of the amputated stump. All four patients in whom the leg was amputated below the knee were diabetic. This is consistent with the previously mentioned observation that those patients having only arteriosclerosis obliterans in whom amputation was performed generally had more extensive arterial disease proximal to the knee, with a higher level of nonfilling, than did those who also had diabetes. The inadequate blood supply in the knee region necessitated supracondylar amputation. On arteriography, two of the eight patients in whom supracondylar amputation was subsequently performed showed vessel filling that extended to the lower leg; however, a lower level of amputation was impossible because both patients were diabetic and had extensive inflammatory skin changes extending well up the leg.

CONCLUSIONS

Femoral arteriography is an essential component of clinical evaluation of arteriosclerosis obliterans. It is the only procedure by which the presence of segmental occlusion can be substantiated; thus, it provides the only adequate means for selecting suitable candidates for treatment by arterial grafting. It is an important means of determining the prognosis of a limb affected by arteriosclerosis obliterans, and it is used to indicate the optimum level of amputation when that is necessary. It is an aid in making the differential diagnosis of peripheral vascular disease.

Treatment of Infectious Hepatitis.—Since physical activity to the point of fatigue may be harmful, patients with acute hepatitis should be hospitalized as soon as the diagnosis is made. They should be urged to rest in bed as long as acute symptoms persist. Once they begin to feel well, regardless of the degree of jaundice, they should not be forced to stay in bed more than 1 hour after each meal. Restriction to the hospital ward, however, is essential to decrease undue activity or exertion. Allowing ad lib. activity on the ward (without any required exertion) circumvents the usual delay necessary for recuperation from the effects of prolonged rest in bed and appreciably shortens the period of hospitalization. Patients so treated may be discharged from the hospital and physical reconditioning may be undertaken after the total serum bilirubin concentration is below 1.5 mg. per 100 ml. and the bromsulphalein retention in 45 minutes below 6 per cent for a period of not less than 1 week. . . . Following discharge from the hospital it is well to follow all patients for 2 weeks with weekly physical examinations, serum bilirubin and bromsulphalein tests. Recurrent abnormalities will occur rarely and are probably indications for rehospitalization. The optimal diet in the treatment of infectious hepatitis consists of about 3,000 calories containing approximately 150 grams each of protein and fat. . . . The fat contained in meat, eggs, and dairy products is not harmful and adds greatly to the palatability of the diet. During the stage of severe anorexia the patient should be urged to take frequent small feedings. Intravenous glucose solutions should be administered when necessary to maintain a minimal caloric fluid intake. Although the forcing of a high-protein, high-fat diet . . . has been demonstrated to hasten recovery . . . critically ill patients with fulminating disease or impending hepatic coma may be harmed by excess dietary protein. In these few patients, therefore, it is probably unwise to administer more than a maintenance quantity of protein. Intravenous protein hydrolysates, plasma or blood transfusions have no place in the nutritional therapy of patients with uncomplicated infectious hepatitis.—T. C. Chalmers, M.D., R. D. Eckhardt, M.D., W. E. Reynolds, M.D., and others, The Treatment of Acute Infectious Hepatitis, *The Journal of Clinical Investigation*, July (Part 2), 1955.

CLINICAL AND ANGIOGRAPHIC CORRELATIONS IN ARTERIAL STENOSIS

Geza de Takats, M.D., Chicago

Not more than 30 years ago surgeons could do no better than amputate a gangrenous extremity after all conservative measures had failed. In the late 20's and early 30's our service began to perform two operations that saved many limbs. Embolectomies were done and are still being done in the first 6 to 10 hours after development of an acute embolism to the lower extremities.[1] Sympathectomies were advocated to enlarge the terminal capillary bed and to decrease the resistance in collateral vessels in patients with occlusion of the major arterial pathways.[2] Today, another step forward may be made by recognizing and treating arterial stenosis, the forerunner of many vascular catastrophies.[3] When peripheral embolism and thromboangiitis obliterans are excluded, both of which may produce stenosis by partial canalization of the clot, the overwhelming problem is that of the arteriosclerotic patient whose subintimal atheroma protrudes into the wall, narrows the lumen,

rmittent
ich he wants
nd partly on *whether the patient is walking on soft grass as against pavement, on even ground as against climbing stairs, and in the manner of a carefree saunter as against a hurried trot to catch the 8:06 a. m. train.* Since, however, there is no rest pain, there is evidence of sufficient basal blood flow that only becomes inadequate on increased demand from the contracting muscle. The active muscle may abstract almost all the oxygen brought to it in the arterial blood, and the blood flow may rise as high as 30 times its basal value.[4] For this reason, in an incomplete arterial obstruction, an arterial stenosis will first manifest itself during exercise. The difference in pulses is an objective finding of diminished inflow. Frequently, one femoral pulse is weaker than the other, and this finding, coupled with cramping in the buttocks or posterior muscles of the thigh, indicates an iliac occlusion. The two posterior tibial arteries may differ from each other, and, should the claudication be in the calf, the site of obstruction is apt to be at a femoropopliteal level. Any doubtful differences can be confirmed by a study of the patient after exercise, when an existing pulse may disappear or the needle of an oscillometer may stop swinging (fig. 1). The oscillometer may also give an idea of existing collateral circulation and the presence or absence of any total occlusion of the main channel. The pulsations may be intense and rapid, although diminished in size, indicating narrowing of the vessel, or they may show a slow worm-like movement, which means that a delayed pulse appears through narrow, elongated collateral pathways. The site of abnormal oscillations may help to locate the segmental stenosis.

There are certain sites of predilection in nonembolic arterial stenoses. They are not at bifurcations as are the embolic ones but occur in the common iliacs (as emphasized early by Palma [5]) just below the bifurcation of the aorta; in the hypogastric artery, a short distance from its origin; at the upper end of Hunter's canal (also emphasized by Palma [5]); and proximal to the tendinous arch of the soleus muscle in the popliteal fossa. A mechanical factor in the localization of these atherom plaques is unmistakable. Later, of course, a thron mass may pile up above or below these obstructions, at operation the naked eye can usually detect the starting point of an ascending thrombosis. It is quite possible that the lipid metabolism is the basic underlying factor of atheromatosis,[6] but the mechanical effect on the vessel wall at typical areas of strain is quite evident.

The hemodynamic effect of such a segmental stenosis is variable. It may produce a poststenotic dilatation, the mechanism of which has been thoroughly investigated by Emile Holman,[7] or, because of the marked fall in intraluminal pressure when the stenosis closes more than 75% of the lumen,[8] a thrombosis may occur distally that makes efficient collateral circulation impossible. The wall of the artery distal to a partial occlusion or ligature shows proliferative changes leading to further stenosis or obliteration. Vasomotor reflexes become active.[9] At

any event, the stenotic arterial segment is a source of danger. The roentgenologic examination accurately visualizes and localizes such a segment. The arteriograms presented below, together with brief clinical abstracts of the cases, illustrate the different types of occlusion found in common iliac stenosis, which we now frequently encounter.

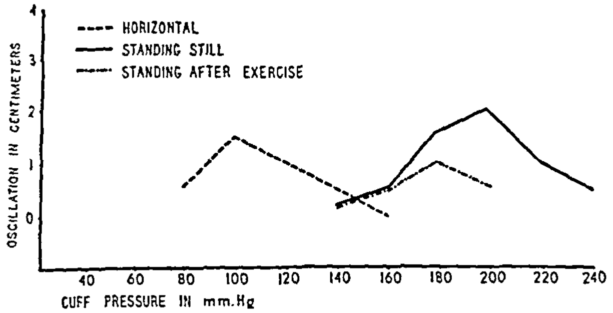

Fig. 1.—Oscillometric curves of 42-year-old male with mild claudication in the left thigh and calf in horizontal and standing positions and immediately after exercise. All pulses were palpable although slightly diminished. On standing, the oscillometric curve is higher, with a shift to the right, indicating increased resistance. (This postural vasoconstriction can be overcome by sympathectomy.) After exercise, the curve becomes flatter, which is an abnormal response.

ARTERIOGRAMS

Two sites of injection are used to visualize the arterial tree of the lower extremities; that is, at the aortic level and at the common femoral level. The aortic injections may be high, just under the diaphragm, in order to see the renal and adrenal circulation, or they may be made low, when one is interested in the area of the aortic bifurcation and the two iliacs. The superficial femoral artery often becomes ragged and narrow at the upper end of Hunter's canal and may produce symptoms before it is completely occluded, although one can never be sure that some of the muscular branches in the calf are not causing the claudication. In figure 2*A* an early stenosis of the superficial femoral artery is seen, and in figure 2*B* a very short and not quite complete obliteration is visible. Stenosis (fig. 2*A*) was undisturbed, and high lumbar sympathectomy improved the patient's ability to walk without pain from two to six blocks; in the patient of figure 2*B*, who could not walk more than three blocks without pain in the left calf, lumbar sympathectomy and resection of a short arterial segment with direct anastomosis completely restored his walking ability.

In many patients the occlusion is almost complete, and a sturdy short collateral makes the arterial flow detour. Lumbar sympathectomy, resection of the occluded segment with careful saving of the collaterals, and an autogenous vein graft restores the circulation in about 80% of the patients. In the hospital with which I am affiliated, there is a large number of patients with completely occluded superficial femoral, deep femoral, and posterior tibial arteries. I shall not discuss these except to emphasize that any of the early incomplete and short stenoses may suddenly become completely occluded and cause severe ischemia or even loss of limb. In the case of one patient suffering from a popliteal atheroma, an emergency lumbar sympathectomy was done because of a sudden popliteal arterial thrombosis. No at[illegible] made to ream out the popliteal segment, and the went back to work as a hospital employee. Seven weeks later he had another episode, this time occluding a long segment of the superficial femoral artery, thus destroying an abundant collateral network just above the previous occlusion. This second ascending thrombosis resulted in his losing the extremity above the knee. Such experience and others would suggest that all acute occlusions, not only the embolic but the thrombotic ones as well, should be removed if possible, since they carry the danger of additional superimposed occlusions that may not permit the extremity to survive.

Since most physicians are now surely familiar with the full-blown picture of thrombosis at the bifurcation of the aorta, a few arteriograms can be shown of the incomplete stenosis of the iliacs or the terminal aorta itself. In the case of one patient, who complained of claudication of buttocks and thighs, with loss of erection, a large atheroma was seen at the lower end of the aorta, and both iliacs showed spots of decreased opacity indicating areas of atheroma, usually situated on the posterior wall of the artery (fig. 3). In the case of another patient, the stenosis is at the bifurcation due to plaques on the posterior surface of the aorta, extending more into the left than into the right common iliac artery. These plaques were removed by endarteriectomy (fig. 4). In another patient, whose symptoms date back to a severe fall over the left flank and buttocks, the pain in the buttocks and thigh became progressively worse. In the arteriogram of this patient an early stenosis of the right common iliac artery that was verified at operation and a

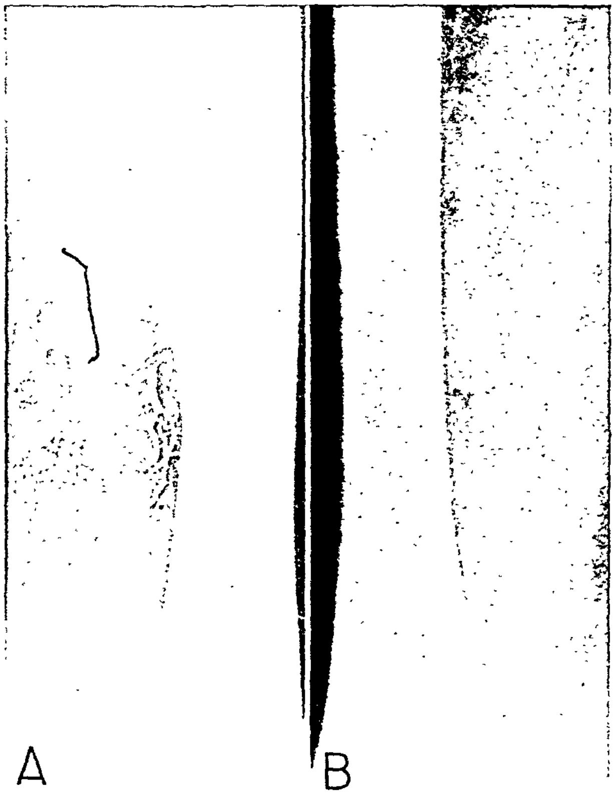

Fig. 2.—*A*, arteriogram of 55-year-old male with mild intermittent claudication and decrease in oscillations after walking. complete obstruction of the left common iliac artery were seen. These were relieved by endarteriectomy, with full restoration of circulation.

MANAGEMENT OF ARTERIAL STENOSES

It is true that the majority of patients suffering from peripheral vascular stenosis come to our attention after an occlusion has taken place. Elsewhere,[10] I have outlined my attempts to revascularize an arteriosclerotic extremity in which the major arterial pathway is occluded. There are more and more cases, however, especially if we study the extremity opposite the affected one, in which clinical and roentgenologic evidence indicates an arterial stenosis. It is here where the difficulty of an optimal course of therapy arises. While certain surgeons are now resecting stenotic segments, it has been our principle to reserve arterial resection and grafting for cases of complete occlusion. The results of resecting and replacing occluded aortic and femoral segments have been reported from our institution.[11] It may well be that with increasing facility of obtaining vascular segments or plastic tubes and with increasing percentage of restoration of arterial flow, one might advocate resecting stenotic segments before they become occluded. At the present time, however, I prefer the following steps before resection and grafting are undertaken: 1. For the superficial femoral and popliteal stenosis, a lumbar sympathectomy often improves claudication. This simply means that the sum total of blood through the narrowed main pathway and the decreased collateral resistance is sufficient to meet the demand of increased flow to muscle. 2. In the case of an acute occlusion of a femoral or popliteal segment, the lumbar sympathectomy is followed by an opening of the vessel and extraction of the fresh clot and the atheromatous core around it. This must be followed by cautious heparin therapy. 3. In the case of an iliac stenosis on one or both sides, a high lumbar sympathectomy is followed by an endarteriectomy of one or both iliac vessels or of the aorta; however, if the occlusion of the aorta is complete, replacement by graft is preferable. It is to be noted that the optimal procedure for high-grade stenosis of the aortic bifurcation is debatable; however, long-term observation will determine the proper course of surgical therapy. I believe that medical therapy is useless in the treatment of arterial stenosis.

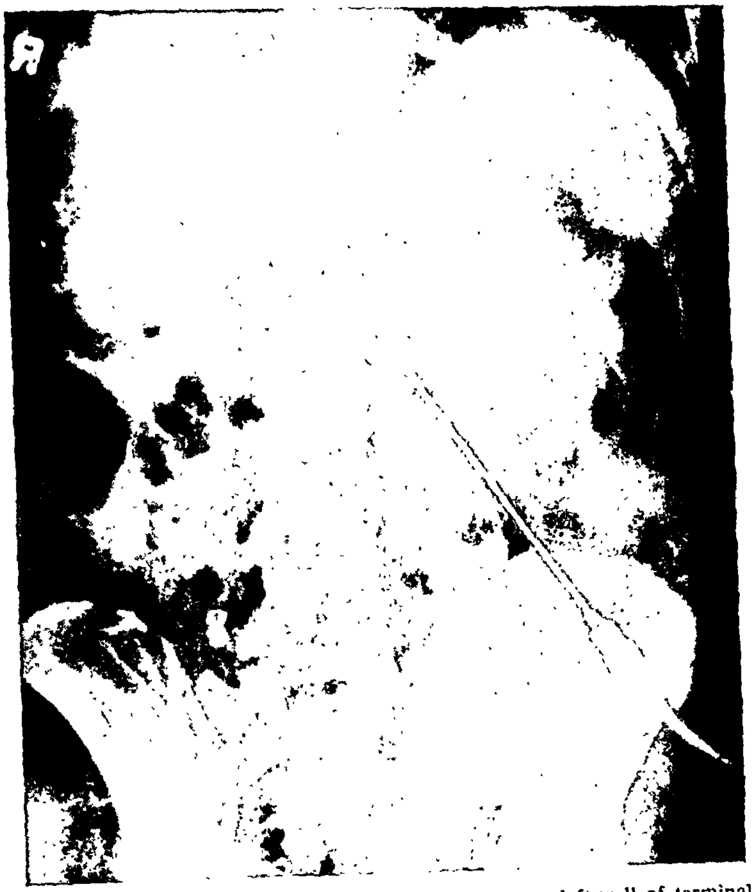

Fig. 3.—Aortogram of male with huge atheroma on left wall of terminal aorta and spots of decreased opacity in both iliac arteries due to saucers of lime on posterior surface. Endarteriectomy was done, which relieved the partial obstruction.

COMMENT

For years to come, early arterial stenosis will probably be discovered only when the contralateral extremity is studied. For years we have practiced "prophylactic" sympathectomies on patients with demonstrable obliterative vascular disease, when the more involved extremity needed sympathectomy or amputation. One would like to believe that such sympathectomies have prevented further deterioration of circulation, but, unfortunately, such is not always the case. It is true that a sympathectomized extremity will better tolerate a sudden popliteal or femoral thrombosis, but we have seen a sufficient number of patients whose second extremity became critically ischemic in spite of previous sympathectomies. For this reason it is now our custom to take a femora arteriogram or aortogram when the clinical examinatio

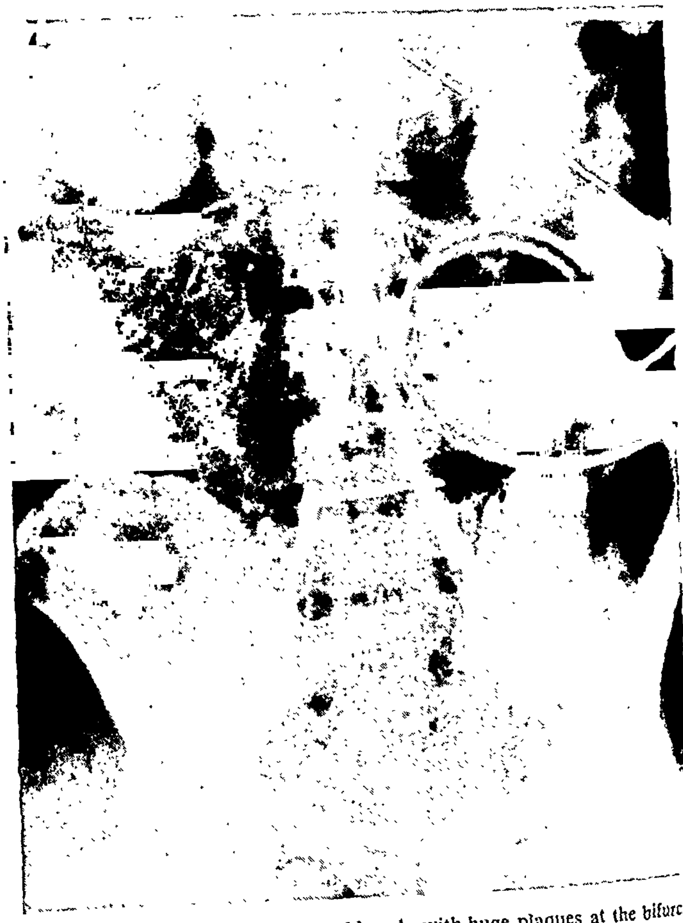

Fig. 4.—Aortogram of 47-year-old male with huge plaques at the bifurcation. Endarteriectomy removed these and restored both femoral pulses. Although this was an incomplete occlusion, his symptoms became progressively more incapacitating.

suggests partial or total arterial occlusion. Should the arteriogram reveal an isolated segmental stenosis, an endarteriectomy must be seriously considered.

Arterial stenosis has a number of hemodynamic consequences.[12] The artery above the occlusion develops a systolic bruit as a result of churning and regurgitation. Plaques are more apt to form here and also thrombi. Distal to the stenosis one may find aneurysmal dilatation,[7] but most of the time the fall in blood pressure and the slowing of circulation will produce intimal proliferation or thrombosis. Collateral circulation does not always keep pace with arterial occlusion, and progressive ischemia calls for active surgical intervention.

SUMMARY

Arterial stenosis can be recognized by clinical and roentgenologic means before an acute vascular accident or a diffuse obliterative vascular disease develops. Preventive surgery consisting of sympathectomy and endarteriectomy are particularly indicated in those persons whose opposite extremity is the site of a critical vascular lesion leading to gangrene.

COMPARATIVE EFFECTS OF PREDNISONE AND CORTISONE

Felix Demartini, M.D., Ralph H. Boots, M.D., Arthur I. Snyder, M.D., John Sandson, M.D.
and
Charles Ragan, M.D., New York

Prednisone (Meticorten) was introduced in November, 1954, as an effective antirheumatic medication.[1] In animals, it was found to produce involution of the thymus, eosinopenia, and glycogen deposition in the liver, as do cortisone and hydrocortisone. The similarity to cortisone in its molecular structure[2] and biological effects led us to compare the two compounds and attempt to assess the possibility of prednisone supplanting cortisone. The work was done in human subjects with rheumatoid arthritis, systemic lupus erythematosus, pemphigus, periarteritis nodosa, and diabetes mellitus associated with the nephrotic syndrome. One additional study was carried out in animals by the Selye granuloma pouch technique.[3]

SODIUM, POTASSIUM, WATER, AND GLUCOSE METABOLISM

Two patients with well-documented sustained rheumatoid arthritis of more than five years' duration were admitted to the metabolism ward of the Presbyterian Hospital, New York. Both patients were placed on a constant diet and given prednisone, 30 mg. in 24 hours in four divided doses. Daily clinical observations were made, and 24-hour urine specimens were collected throughout the study period for sodium and potassium analysis. The results of this study on two patients (cases 1 and 2) are recorded in figure 1*A* and *B*. The dosage of prednisone administered produced definitive antirheumatic effects as measured by symptomatic and objective improvement. It can be seen that this was accomplished without evidence of sodium or water retention. A transient 24-hour potassium diuresis of unknown significance was noted. However, in a dose of 100 mg. per 24-hour period, one patient with pemphigus, not on a balance but receiving approximately 4 gm. of sodium chloride per 24 hours, gained 10 lb. (4.5 kg.) in one week. This was associated with the development of marked dependent edema, and, when sodium was restricted to approximately 1 gm. per day, a prompt diuresis of 10 lb. (4.5 kg.) occurred in four days.

After three weeks of therapy with 30 mg. per 24 hours of prednisone, the sodium intake was restricted to less than 10 mEq. per 24 hours. Despite this severe sodium restriction, the patients of cases 1 and 2 (fig. 1*A* and *B*) were promptly able to conserve sodium. Another patient (case 3), with periarteritis nodosa, was placed on a constant diet, and 24-hour urine specimens for sodium and potassium were collected (fig. 2). He had been receiving 35 mg. of the hormone per 24 hours for three months. At this time he failed to respond to 25 units of corticotropin given intravenously as determined by plasma concentrations of 17-hydroxycorticosteroids.[4] He received 79.6 mEq. of sodium and 110.8 mEq. of potassium in 24 hours in his diet for six days, and urinary 24-hour sodium and potassium levels were determined. While diet and potassium intake stayed constant, sodium was restricted to 10.6 mEq. per 24 hours, and it can be seen that he promptly conserved sodium.

Before administration of prednisone, two patients (cases 1 and 2) had normal blood sugar levels two hours after eating a meal containing over 50 gm. of carbohydrates. Repeat observation on the two-hour post-

prandial blood sugar level was made after one week of treatment with prednisone, 30 mg. daily. Serum glucose values remained within normal limits, showing no hyperglycemic effect in the nondiabetic patient. On the other hand, a 15-year-old Negro male (case 4) with adequately controlled diabetes mellitus and the nephrotic syndrome was given prednisone in doses ranging from 30 to 50 mg. per day in four divided doses. It can be clearly seen (fig. 3) that a marked interference with carbohydrate metabolism developed. This was manifested by marked hyperglycemia and heavy glycosuria necessitating that his daily insulin requirement for only partial control be doubled. It can also be seen that upon the discontinuation of prednisone, effective diabetic management was again resumed at a level of insulin dosage close to his pretreatment requirement. It is interesting to note that on the 14th day of prednisone administration, diuresis began, resulting in a weight loss of 55 lb. (25 kg.) and complete clearing of the nephrotic picture.

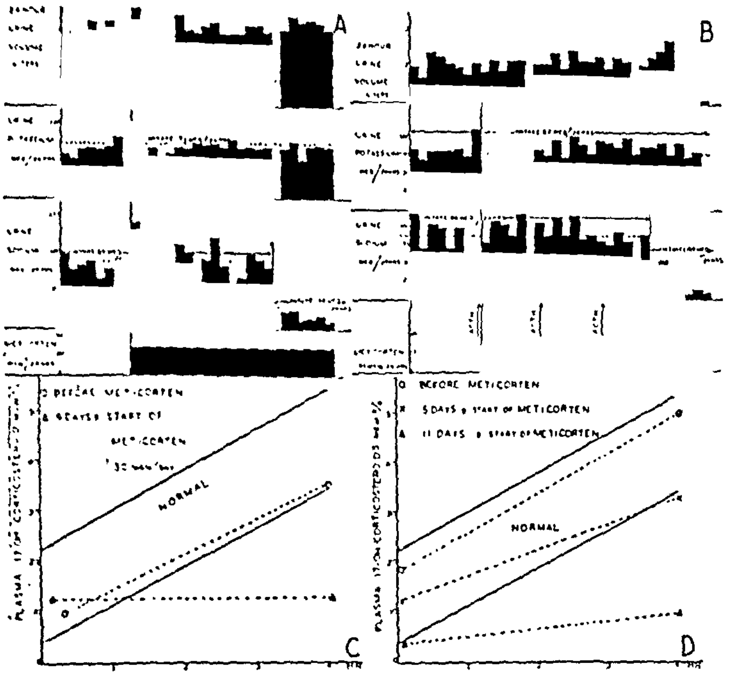

Fig. 1.—Effect of prednisone (Meticorten) on sodium, potassium, and water balance in patients with rheumatoid arthritis. *A*, case 1. *B*, case 2. Plasma 17-hydroxycorticosteroid. Response to corticotropin, 25 mg., given intravenously. p' means after. *C*, case 1. *D*, case 2.

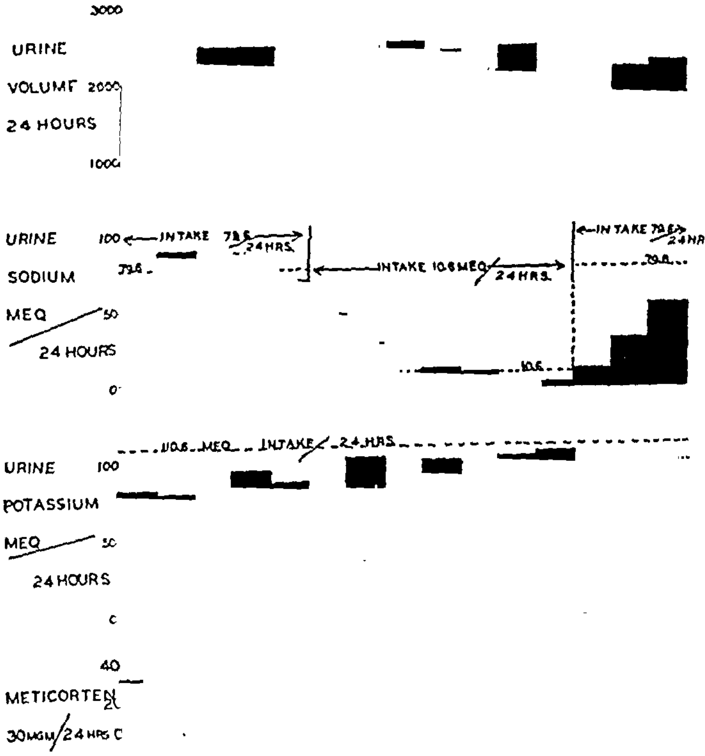

Fig. 2.—Sodium deprivation in patient with periarteritis nodosa receiving prednisone for three months (case 3).

ADRENAL CORTICAL FUNCTION

Two patients (cases 1 and 2) exhibited normal responses in their plasma levels of 17-hydroxycorticosteroids[4] to the administration of 25 units of corticotropin before prednisone therapy as shown in figure 1*C* and *D*. After 9 and 11 days, respectively, of therapy, these patients had a definitely subnormal response. One other patient (case 5), with severe rheumatoid arthritis of seven years' duration, exhibited a normal response to intravenously administered corticotropin after three years of daily oral treatment of 50 mg. of cortisone, but a subnormal response after 13 days of 30 mg. of prednisone daily (fig. 4).

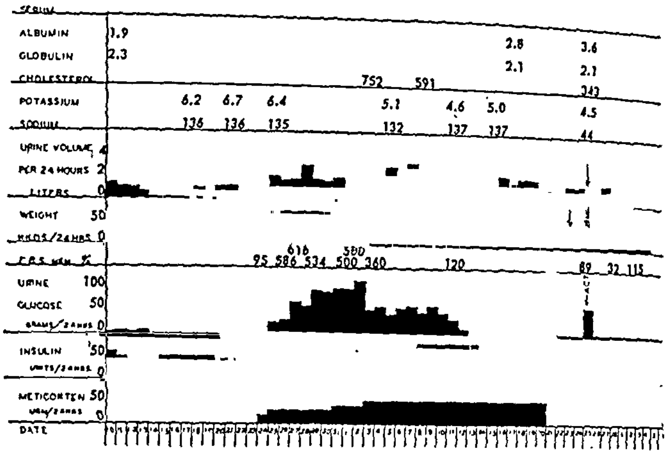

Fig. 3.—Effect of prednisone on glucose metabolism and nephrotic syndrome in patient with diabetes and the nephrotic syndrome (case 4).

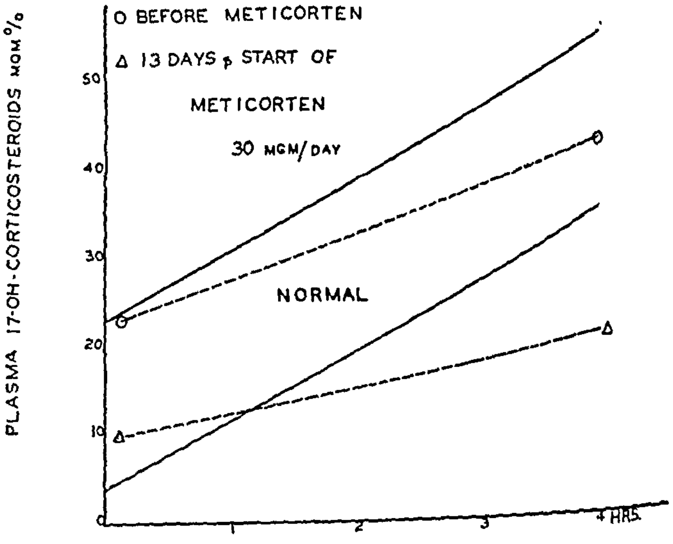

Fig. 4.—Plasma 17-hydroxycorticosteroid. Response to corticotropin, 25 mg., given intravenously (case 5). p' means after.

ANTI-INFLAMMATORY EFFECT ON RATS

Granuloma pouches were made in 26 rats by the Selye technique. Nine animals served as controls and received 1 cc. of saline solution administered subcutaneously twice a day; eight animals received cortisone, 1 mg. subcutaneously twice a day; and nine animals received prednisone, 1 mg. subcutaneously twice a day.

The results are charted in the table. There was a marked reduction in the weight of the granuloma membrane in both the cortisone-treated and prednisone-treated animals after one week of treatment.

ANTIRHEUMATIC PROPERTIES

We have been interested in comparing the clinical aspects of the antirheumatic properties of prednisone to those of cortisone. Patients with rheumatoid arthritis maintained on long-term suboptimal therapy with cortisone were given prednisone. The suboptimal end-point in therapy has been taken as that amount of steroid required to keep these patients ambulatory and effective, if possible. We chose a starting dose of prednisone as 30 mg. in 24 hours in divided doses. Patients with rheumatoid arthritis suboptimally controlled on 75 to 100 mg. of cortisone were maintained ambulatory with prednisone in doses between 20 and 25 mg. Erythrocyte sedimentation rates, elevated on 100 mg. of cortisone, became normal with the above doses of prednisone. We have noted in patients receiving prednisone the same complications of adrenal cortical hyperfunction (Cushing's disease) as is seen with cortisone. Cushing's facies have developed within two weeks on 20 mg. of prednisone per day. One patient with systemic lupus erythematosus developed a frank psychosis with hallucinations during daily doses of 50 mg. similar to a previous psychosis that appeared while she was receiving cortisone. Severe tension states that had developed in two patients with rheumatoid arthritis while taking cortisone have persisted on doses of prednisone that were one fourth of the cortisone dose. A duodenal ulcer, demonstrated by gastrointestinal x-ray series, developed in a patient with rheumatoid arthritis after two weeks of prednisone treatment. A patient with periarteritis nodosa developed a large gluteal abscess, unaccompanied by systemic symptoms and with a marked inhibition of granulation tissue during the administration of prednisone. It has also been our experience that the management of patients with rheumatoid arthritis, systemic lupus erythematosus, and periarteritis has been very similar to that of those patients treated with cortisone. If the amount of prednisone is reduced below that required to suppress inflammation, the symptoms of their disease have returned, usually within 24 hours. Symptomatic and objective evidence of active disease can again be suppressed only with increasing the amount of prednisone administered.

COMMENT

There are no data available to indicate that the antirheumatic and antiphlogistic actions of prednisone differ qualitatively from those of cortisone. This is shown by the fact that we have seen the development of Cushing's facies, difficulty in the control of infection, psychosis, retention of fluid with large doses of prednisone, interference with glucose metabolism, activation of duodenal ulcer, and the prompt return of symptoms upon cessation of treatment with this steroid in patients with active rheumatoid arthritis. This is also supported by the observed decrease in size of granuloma membrane, thymic involution, eosinopenia, and increased glycogen deposition in the liver in animals receiving prednisone. The transient diuresis of sodium and potassium seen in two patients (cases 1 and 2) with active rheumatoid arthritis cannot be attributed to any diuretic property per se. These two patients had an active systemic inflammatory disease with large joint effusions and surrounding soft tissue edema. It is possible that a release of electrolyte from these inflamed areas may have occurred secondary to the antiphlogistic action of prednisone.

We were concerned regarding the lack of response of the adrenal cortex to the administration of corticotropin in patients receiving prednisone. The administration of cortisone has been observed to produce the same effect. However, the amount of cortisone needed to control the symptoms of rheumatoid arthritis has more sodium-retaining and water-retaining properties in the patient with a normal-functioning adrenal gland and would tend to protect the patients from an "Addisonian-like crisis." It is reassuring to see that sodium conservation can occur in the prednisone-treated patient on severe sodium restriction despite the fact that it interferes with the production of 17-hydroxycorticoids in the plasma following corticotropin administration. There are no data available at this time on the complications of prolonged administration of this hormone. From this discussion, it would appear that the postulated mode of action in suppressing inflammation is qualitatively similar to that suggested for cortisone. The interference with tissue turnover should be followed in time by complications such as osteoporosis and compression fractures.

Comparative Effects of Prednisone and Cortisone on the Granuloma Pouch Weight in Rats

Therapy, for 1 Wk.	Granuloma Pouch Mean Wet Wt., Gm.	Adrenal Wt., Gm.	Body Wt., Gm.	
			Initial	Final
Saline solution in 9 animals..........	3.5	50.4	141	182
Cortisone in 8 animals, 1 mg. subcutaneously, twice daily............	1.8	24.4	138	130
Prednisone in 9 animals, 1 mg. subcutaneously, twice daily............	1.3	40.5	136	123

Sodium retention with edema has been a frequent occurrence in our experience in the long-term cortisone therapy of rheumatoid arthritis. It has been possible to control this with relatively simple cardiotonic and diuretic measures in most instances. Potassium loss in our cortisone-treated patients has been of negligible importance and potassium supplementation has been required only rarely. At this time, prednisone has been demonstrated to be superior to cortisone in only one aspect, namely, that it has a lesser potential for sodium and water retention, and potassium diuresis at doses effective as an antirheumatic agent. Long-term therapy is, however, fraught with many hazards, and the abolition of one or two would be of great help to the patient and physician. We believe that the decreased salt-retaining and potassium-losing properties of prednisone at dosages required for suboptimal control of most patients with rheumatoid arthritis warrant its use in preference to cortisone and that prednisone will supplant cortisone as an anti-inflammatory agent.

SUMMARY

Reported clinical studies have shown that prednisone has the following biological properties: (1) effective anti-inflammatory and antirheumatic properties demonstrated in humans and rats; (2) interference with glu-

cose utilization; (3) ability to suppress elaboration of 17-hydroxycorticoids by the adrenal cortex following intravenous administration of corticotropin; and (4) anti-inflammatory property is quantitatively, milligram for milligram, greater than cortisone, thereby permitting less sodium and water retention and potassium diuresis at dosages needed for symptom control in rheumatoid arthritis. We believe that qualitatively the mechanism of its anti-inflammatory and antirheumatic action is similar to cortisone and that prednisone is preferable to cortisone as an anti-inflammatory agent.

620 W. 168th St. (32) (Dr. Ragan).

BREAKING THE SOUND BARRIER AND ITS EFFECT ON THE PUBLIC

Col. John M. Talbot (MC), U. S. A. F.

Theory tells us that whenever an object speeds through the atmosphere at the velocity of sound, or faster, it generates a compression wave or shock wave that is similar to a high explosive blast wave. The ear perceives a definite boom, and the skin pressure receptors may sense a momentary concussion. Sonic boom is currently the popular term for the phenomenon. Through all of history, hearing beings have occasionally been startled by the explosions of meteorites crashing down through the atmosphere, our earliest example of the sonic boom. More familiar examples are the sharp crack of a passing rifle bullet and even the explosive pop of the lion trainer's whip as it accelerates for an instant beyond the speed of sound.

The foundation of our present supersonic jet era embraces a fascinating story of concentrated aeronautic research and development effort and heroic test flights in an international race to achieve the great tactical advantages of ever swifter flight and higher altitudes. Only some highlights can be mentioned here. The United States officially entered the race in 1944 when the Air Force, Navy, and National Advisory Committee for Aeronautics jointly launched the high speed flight research program. The Bell Aircraft Corporation won the first design competition for a transonic research aircraft and was awarded a contract in May, 1945, to build the first of its famous research series of rocket powered airplanes, the XS-1. The Douglas D-558-1 Skystreak and D-558-2 Skyrocket spearheaded the second important series of research aircraft. The first pilot to break the sonic barrier was Major (then Capt.) Charles E. Yeager, who, on Oct. 14, 1947, flew the Bell XS-1 faster than 1,600 miles per hour and higher than 70,000 ft., establishing unofficial world's records for both speed and altitude. Steady progress followed in both the Bell and Douglas experimental series. The first production-type military airplane to exceed Mach 1.0 (sonic speed) was the North American F86-A, a swept wing fighter, now renowned for its magnificent record against the Reds in Korea.

As pointed out by Corey Ford,[1] during the period January, 1951, through October, 1953, a sporadic series of startling and unexplained explosions occurred in widely scattered communities in the United States and Canada. Meanwhile, experience in test diving new jet fighters to and beyond the velocity of sound ultimately demonstrated that here, previously unsuspected, was the cause of the disturbing blasts. Prompt remedial steps were taken by the Air Force and the aircraft industry to control flight operations so that populated areas would experience a minimum of these annoyances.

This paper has two purposes: to review and interpret some of the facts and theories about the sonic boom and its effect on the public, in the hope that a wider understanding of this phenomenon by the medical profession will aid in reassuring the American public and in promoting a readier acceptance of our vital supersonic defense weapons; and, secondarily, to indicate briefly what the Air Force is doing about control of aircraft noise in general.

GENERATION OF THE SONIC BOOM

To begin with, let us consider the current theory of the sonic boom as caused by super fast aircraft. In order not to complicate the basic concept, assume ideal atmospheric conditions; i. e., still air of uniform temperature and density. Diagram *A* of figure 1 shows the radial propagation in all directions of pressure disturbances from a fixed sound source in the air, as from the engine of a hovering helicopter. These waves move at the velocity of sound, which in still air at sea level and 20 C is about 1,100 ft. per second, or 760 miles per hour. For airplanes moving near the speed of sound or faster, it has become customary to express the velocity in Mach numbers, defined as the ratio of the velocity of the aircraft to the velocity of sound under the attendant atmospheric conditions. Hence, in a standardized situation of average sea level air, an airplane moving at 760 miles per hour has a velocity of Mach 1.0. As a rough index, the speed of sound varies from 760 miles per hour at sea level to 675 miles per hour at 30,000 ft. Diagram *B* illustrates the effect of motion through the air of the sound source, in this case an aircraft moving at less than the speed of sound. Note that the sound waves are still propagated in a radial distribution in all directions but that those racing along the flight path tend to be crowded together into a higher frequency as compared with those emitted in the opposite direction. This is a graphic illustration of the Doppler effect, familiar to many as the sudden drop in pitch of a train whistle as the train flashes

Read before the Section on Military Medicine at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

The discussion of this paper was opened by Dr. Aram Glorig and Major Sidney I. Brody.

The technical data on which this paper is based are from the Air Research and Development Command Research and Development Program in Noise and Vibration Control.

[1] Ford, C.: The Truth About the Sonic Boom, Sat. Eve. Post 227: 26 (Dec. 4) 1954.

close by. Next, consider the effect of the aircraft moving at supersonic speed, as shown in diagram *C*. In this case, the air frame itself, nose, wings, and tail, is the source that generates the most striking pressure disturbances in the air; at supersonic velocity, it actually moves ahead of the successive pressure rings it generates. As indicated in the drawing, successive disturbance rings become tangent to a line sloping away from the source at an angle, reinforcing each other and joining to form larger disturbances known as shock waves. The angle between the shock wave and the flight path is called the Mach angle, and it varies inversely with the speed of the airplane.

PROPAGATION OF SONIC BOOM

To date, the sonic booms that have reached ground level have been produced only by diving maneuvers and by relatively low altitude fly-bys; nevertheless, because it is theoretically possible for the shock waves from a supersonic aircraft flying straight and level to reach the surface, operational policy requires supersonic flights over populated areas to be at 30,000 ft. or above. A comparison between the effect of diving through the speed of sound and of flying level above Mach 1.0 is shown in figure 2. The compound nature of the shock front is suggested by the dense shading of the leading part, to represent increased pressure, and the light shading of the trailing part, to represent decreased pressures, all relative to the ambient atmospheric pressure. In the case of the dive, the airplane, flying at less than Mach 1.0 enters a downward flight path and accelerates past Mach 1.0, generating a continuously growing shock front that travels toward the ground. Although measured data are incomplete as yet, the sonic booms during diving maneuvers and 10,000 ft. altitude fly-bys have been observed to spread over areas varying in diameter from 15 to 35 miles. In practice, it is possible for the pilot in a dive to aim the shock wave toward a ground target with fair accuracy. The right-hand diagram illustrates shock wave propagation to the ground in the case of level supersonic flight. It is apparent that the shock wave moves along the surface in the direction of flight and may therefore sweep a path approximately equal in length to the level supersonic flight path of the source airplane. This is in contrast to the focusing effect resulting from the dive. This diagram has been simplified to the point that only the primary shock wave has been shown, as it is the principal one of concern in this paper. Actually, separate shock waves may arise from several presenting surfaces of the airplane such as nose, windscreen, wings, and tail.

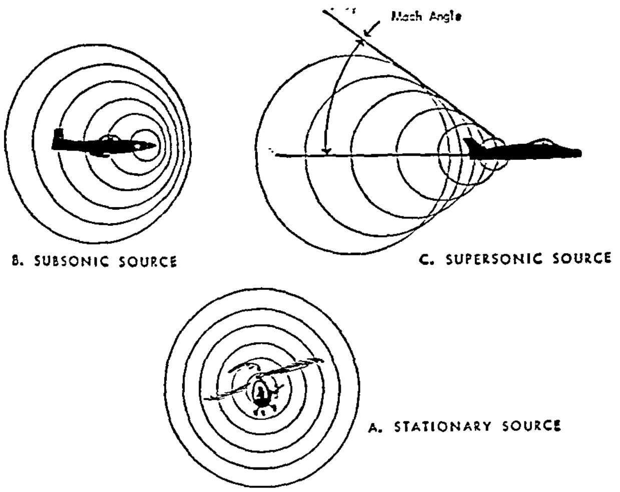

Fig. 1.—In situations *A* and *B* sound waves radiate in all directions from source. Airplane in diagram *C* flies faster than sound, trailing succession of sound waves that form reinforced pressure front called shock wave.

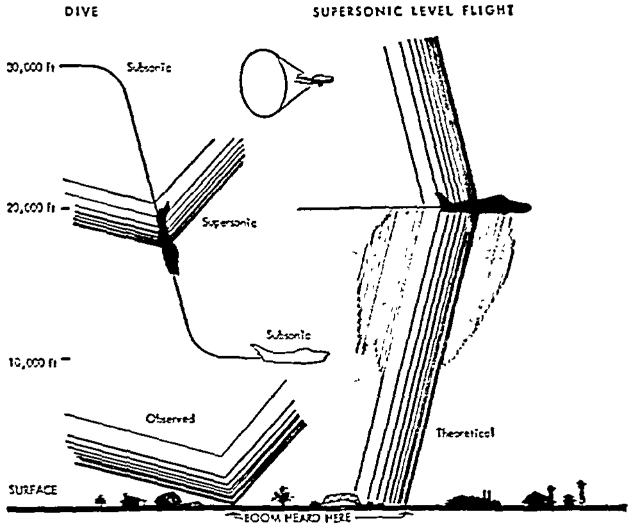

Fig. 2.—Airplane on left dives at supersonic speed, generating shock wave that is transmitted to surface along line of flight. Shock waves from supersonic airplane in level flight can theoretically reach ground, as shown in diagram on right.

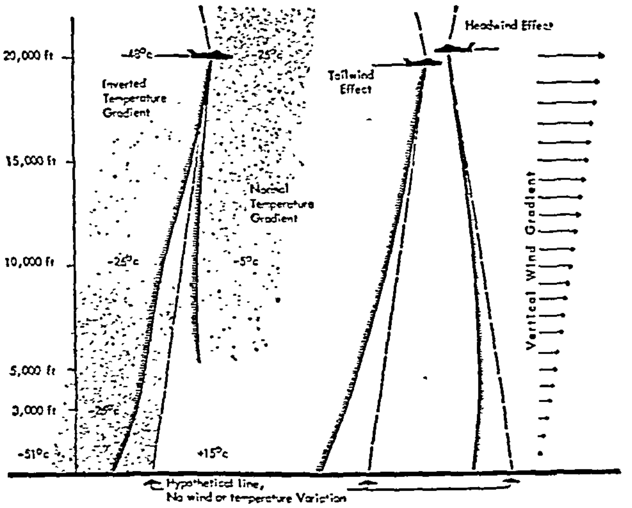

Fig. 3.—Effects of temperature and winds on shock waves. Altitude in thousands of feet is shown as ordinate. Evaluation of possible importance of these variables on shock wave transmission is in progress.

FACTORS THAT INFLUENCE TRANSMISSION OF SHOCK WAVES

One may ask, "What are the important factors besides speed and direction that influence the transmission of the sonic boom?" There are many, but the most significant appear to be air density, atmospheric temperature, winds, and distance from the source to the observer. Figure 3 illustrates the effects of vertical temperature gradients and wind gradients up to 20,000 ft. In each diagram, the dashed lines extending to the surface indicate the theoretical transmission of shock waves in still air of uniform density and temperature. It may be seen that the normal temperature gradient causes the shock wave to move faster as it enters higher temperature levels nearer the ground; the shock wave terminates at the altitude at which the velocity of sound equals that of the source aircraft (shown by the end of the solid line). Conversely, in the inverted temperature gradient situation, the shock wave is swept back into an exaggerated trailing position relative to its source. The influence of the normal vertical wind gradient may be seen in the right-hand diagram. A head wind gradient, with high winds aloft and lesser winds near the surface, allows the shock wave to bend forward of the undisturbed theoretical line; conversely, in the case of the vertical tail wind gradient, the waves are bent rearward.

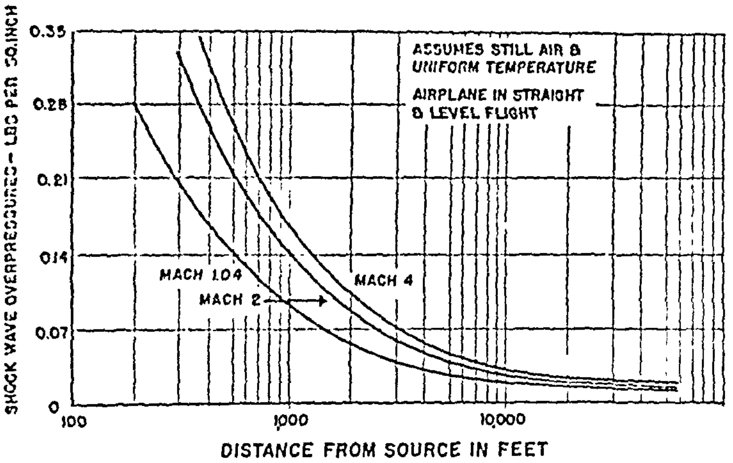

Fig. 4.—Theoretical shock wave overpressures as function of speed and distance. Note that beyond 5,000 ft. from source, influence of speed of source on shock wave pressures is negligible. These figures contrast with blast wave overpressures; e. g., 5 lb. per square inch from 20 kiloton atomic explosion at 5,000 ft.

NATURE OF THE SHOCK WAVE

What is the nature of the shock wave? It is not unlike the blast wave (minus windage or gust effects) of a high explosive detonation or even of a nuclear detonation, the essential differences being duration and degree of pressure differential across the shock wave. All have these factors in common: they originate from a center of high compression, travel supersonically at first, then at sonic speed; and they have a characteristic triphasic history of initial overpressure build-up followed by decompression below atmospheric and recompression to ambient level. In the case of the sonic boom, the initial phase or compression wave is heard as the first boom; the final phase, or recompression to normal, as the second boom. A typical time sequence for this chain of events occupies about 0.1 second, which is much longer than the shock wave of the conventional high explosive bomb but shorter than that of the nuclear explosion. Figure 4 gives an idea of the pressure rises measurable across sonic boom shock waves and of the influence of distance and velocity of the source. It is seen that, especially at distances beyond 5,000 ft., the effect of speed is very small. The attenuating effect of distance is clearly shown. In contrast the peak overpressure for a 20 kiloton nuclear explosion measured at 5,000 ft. is approximately 5 lb. (2.3 kg.) per square inch, or more than 140 times greater than the shock force that would theoretically be felt from a jet airplane moving at Mach 2 at an equal distance. Extensive research has shown that man is remarkably resistant to blast effects as compared with such familiar structures as average buildings and aircraft. One threshold figure frequently seen in the literature for primary blast damage to man is 50 lb. (22.7 kg.) per square inch peak overpressure; ordinary aircraft on the ground are disabled by 5 lb. per square inch peak overpressure. Although the physical characteristics of the sonic boom are not completely known, the evidence to date suggests that it should be possible to extrapolate directly, albeit roughly, from the more familiar biological effects of high explosive and nuclear blasts to the likely effects of supersonic flight shock waves. On this basis we should expect no serious direct hazard from the latter.

DAMAGE POSSIBLE FROM SHOCK WAVES

In contrast to this, although the amount of damage to buildings and other structures that can be caused by the sonic boom has not been completely determined, the record shows that the numerous booms that were unwittingly directed against the public during early supersonic test dives resulted in a few instances of shattered windows, cracked plaster, and objects knocked off shelves. The most striking examples of damage accompanied the low altitude supersonic runs of the North American F-100. For instance, at Palmdale, Calif., the airport administration building suffered many broken windows, broken wooden door frames, and cracked 4 by 4 in. wooden beams; and during speed trials over the Salton Sea, damage to windows, door frames, and doors in 17 houses amounted to $3,600.

In this brief introduction to the theory of the sonic boom, it has been shown that whenever an airplane accelerates past the speed of sound it generates a shock wave that may be transmitted to the ground, where it is heard as an explosive boom; that these waves can cause physical damage to buildings; and that distance from the source is the most important attenuating factor. It should be added that there is no known way of avoiding the production of the offending shock waves during supersonic flight, although certain air frame designs that reduce sonic drag hold promise for decreasing the intensity of shock waves and perhaps of partially limiting the extent of their propagation.

It is now appropriate to enquire into the effects on the public that result from breaking the sound barrier. Here, it is desirable for the moment to distinguish between the general nuisance problem of all types of airplane noise and the specific companion problem of the sonic boom. By comparison, the former is most formidable and is the subject of an extensive and costly program of research and control measures in the military services.

PSYCHOLOGICAL AND ECONOMIC EFFECTS OF SHOCK WAVES

The effects of the sonic boom on the public fall into two chief categories: psychological and economic. As was pointed out above, during a 20 month period commencing in January, 1951, the American public was exposed to a number of startling, completely unexpected, and unexplained explosion-like noises at widely scattered places across the nation. On different occasions, public reactions approached panic, with frantic calls to police and fire departments and rumors of sabotage, flying saucers, and airplane crashes. All investigations failed to yield the culprit until the true cause of the disturbances was accidentally discovered at Wright-Patterson Air Force Base, Ohio, during the test diving of a jet fighter. With the discovery of the cause came prompt action to control flight operations, and the mysterious explosions over urban communities ceased. It is clear that the startle reaction was the most noteworthy psychological effect and it follows, the most likely reaction that could lead to panic. To the effective remedy of controlling supersonic flight operations has been added the prophylaxis of public enlightenment about the cause and relative harmlessness of sonic booms. Were it necessary, for hypothetical reasons, to expose a community repeatedly and chronically to the sonic boom, the reaction would probably culminate in a rapidly organized legal assault against the offending agency, for not only would the nuisance effect be severe but also the real or imagined adverse economic influences would blossom. Property values might decline; domestic fowls and animals raised for profit might suffer fear-induced damage, all resulting in true economic loss.

Unlike the sonic boom, the other noises produced by modern airplanes and power plants are at least blessed with a less startling and dramatic mode of onset. This blessing, if such it can be called, is of small comfort, however, when one considers the magnitude of the noise problem faced alike by military and civil aviation. Public complaints about the annoyance and economic damage caused by jet noise reached such a level in 1952 that the Air Force had to resort to extraordinary measures in an attempt to meet the problem. As an example, one complaint, which predicted dire effects on the operation of a long-established boys' school because of an Air Force plan to operate B-47's from the local air base, required eight months of investigation plus the personal attention of the Air Force Secretary and Chief of Staff before the plaintiff could be assured that no real threat to the economy of the school existed. On the other hand, at certain active Air Force bases in this country, the exposure of the surrounding community to the noise of flight operations and engine test noise is unavoidable. As was recently pointed out by Parrack,[2] people living within one mile of an active runway and take-off flight path for modern jet bomber operations are in the zone of interference with communication; between 5,000 ft. and 15,000 ft. away, they are in the zone of general annoyance. Under these and similar conditions, community response varies from complete acceptance at the low noise levels to vigorous legal action when individuals or groups are exposed to sufficient noise to be convinced that they or their property or their businesses will be damaged.

Figure 5 will serve to orient the reader in the matter of relative noise intensities from different types of sources. These are typical noise levels at 300 ft. from the source. Note that as progress is made from conventional propeller drives through supersonic props, turbojets, turbojets with after-burners, and on to rocket engines, our potential for delivering big noises steadily rises. By way of comparison, average conversational speech at 3 ft. measures about 80 db.; 65 db. of noise interferes with loud speech, 120 db. causes physical discomfort, and 140 db. produces pain in the ears.

PROGRAM FOR CONTROL OF NOISE PROBLEM

Recognizing the seriousness of the noise problem, the Air Force has directed a comprehensive and coordinated research and development program for the control of noise and vibration caused by all types of Air Force activities. This high priority program has four main approaches: (1) reduction of noise at its source; (2) methods of attenuating noise during ground operations; (3) biological and psychological effects of noise; and (4) community reactions to noise.

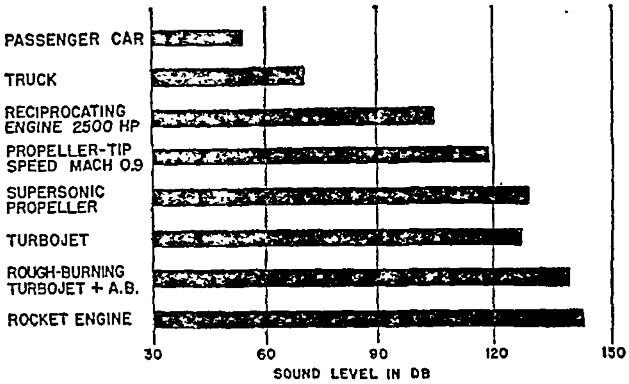

Fig. 5.—Typical over-all noise levels at 300 ft. For comparison, ordinary speech at 3 ft. measures about 80 db.; 80 db. of noise interferes with loud speech; 140 db. causes pain in ears.

The first approach does not appear very promising. Our objective is to keep noise production to a minimum compatible with engine thrust requirements; as thrust increases so does noise. However, a limited improvement may be won by smoothing out the transition to afterburning and by reducing rough burning. Suppression of noise during ground operations offers more leeway, although some of the methods are expensive and cumbersome. As an example, a typical installation to reduce the noise of a jet engine test stand might cost $250,000. Even a simple blast wall for engine run-up costs between $30,000 and $60,000. A partial solution to the community noise problem lies in the application of a series of controls of flight operations; these include routing local air traffic over less densely populated areas, restricting low flying, minimizing exposure to high intensity noise by using high power setting, rapid climbs or low power setting, slow climbs, and adjusting operational schedules when feasible to reduce noise during the more "vulnerable" parts of the 24 hours, such as the hours of sleep.

---

[2] Parrack, H. O.: Protection from Aircraft Noise, A. M. A. Arch. Indust. Hyg. 10:273 (Oct.) 1954.

The program on the biological and psychological effects of noise is directed toward solving the problems of high intensity and of frequent exposures as obtain in the case of jet maintenance personnel and other problems intimately associated with the repair, test, and operation of Air Force equipment. Preventive medical techniques and equipment are the main objectives of this program.

Community relations and public education are believed by many to offer the best approach to a solution of the noise problem. Experience has already shown that a community that understands the problem and knows that all reasonable efforts are being made to control the noise nuisance will adopt a cooperative spirit and an adaptive attitude. Without public understanding and good relations between the air base and the local community, individual and group reactions to aviation noises may interfere seriously with essential Air Force operations. A good example comes from Madison, Wis., where the effectiveness of the local Air Defense Command interceptor unit was threatened by irate citizens complaining that the jet noise intruded on their privacy. The unit commander invited a representative group of the civil leaders to the base for a thorough briefing about the mission of the Air Defense interceptors, a realistic explanation of how Madison is among the American cities lying well within the range of enemy long-range bombers, and a tour of the base to meet the fine young fliers and observe them in action in their vital defensive mission. Public acceptance of the jet noise as an undeniable part of the over-all air defense operation soon became established, and the base has since enjoyed excellent relations with the local community.

To get at the facts of human responses to noise, the Air Force supports research in the following areas: personnel damage, property damage, speech interference, and community annoyance. Of these, the measurement of community annoyance has recently received great emphasis, because it was the least understood and yet possibly one of the most important factors. Even without personnel damage, property damage, or speech interference, people may develop feelings of disturbance, fear, resentment, or even violent hatred in extreme cases of noise intrusion. The objectives of these studies are to understand community responses to noise; to develop methods for predicting community response; and to develop improved techniques for dealing with community annoyance problems.

COMMENT

Thus far, the studies have indicated the importance of several conditioning factors that appear to influence public reaction. Favorable factors include familiarity with the sound and its meaning; a favorable connotation with the sound, such as an appreciation that it stands for national security; an awareness that the noise is unavoidable and/or that all possible steps are being taken to keep the noise to a minimum; and sufficient release of operational information to keep the public appraised of forthcoming operations that may be unusually noisy or that may occur at unusual times during the day or night. Unfavorable factors such as a connotation of the aircraft noise with danger, as might arise from knowledge of recent airplane accidents in the vicinity, tend to increase public annoyance.

Although community reactions seem to be directly proportional to the sound intensity, they do not obey a simple mathematical relationship of this sort; hence, various degrees of reaction may be expected to result from a given level of noise. Besides the sound intensity, many other factors are believed to influence community response—frequency range of the sound, suddenness of onset, time of day or night, frequency of exposure, duration of exposure, and degree of difference from the usual noise background—all are involved, as are economic factors such as businesses and vocations that, by their nature, suffer from aircraft noise.

SUMMARY

Airplanes flying faster than the speed of sound generate a shock wave that may be transmitted to the ground, where it is heard as an explosive boom. Shock waves of this type can cause minor physical damage to windows, doors, and other parts of buildings and adverse psychological effects in exposed populations, such as the startle reaction, fear, and panic tendencies. Restriction of supersonic flying to unpopulated areas and to high altitudes prevents public exposure.

In connection with more general aspects of aviation noise, both military and civil aviation are confronted with an enormously difficult problem of control. Annoyance, anger, and fear as well as real or imagined economic loss are the main public reactions. To meet the problem, the Air Force supports an extensive research and development program aimed at determining the effects of aviation noise on individuals and groups and at improved methods of noise suppression and control. With respect to public reactions to noise, the most promising approach appears to lie in the direction of education and improvement of relationships between air bases and surrounding communities.

Air Research and Development Command, Baltimore.

Renal Function During Anesthesia.—General anesthesia appears to produce a stereotyped response in the kidney dependent in part upon the depth of anesthesia and in no way dependent upon the specific anesthetic agent used. The greater the depth of anesthesia the more profound the changes. These changes consist of a striking intrarenal vasoconstriction associated with a fall in glomerular filtration and a reduction in the excretion of electrolytes and water. There is a relative increase in tubular reabsorption of both electrolytes and water. These changes are extensive and are similar to those seen in other alterations of physiological activity or in a variety of diseased states which may be considered stressful. In the absence of shock and hemorrhage, surgical operation has little influence on these renal functional changes. The precise mechanism of these alterations in kidney function is not known. It appears possible, however, that these alterations are due to an humoral effect, possibly from the adrenal medulla or the adrenal cortex. The striking renal dysfunction which may occur in the postoperative period is not due to the influence of the anesthetic agent but presumably to other factors involving the responses to stimuli from the operative area with subsequent shifts in body fluids.—E. M. Papper, M.D., Renal Function During General Anesthesia, *Bulletin of New York Academy of Medicine,* June, 1955.

UREMIA-LIKE SYMPTOMS NOT DUE TO UREMIA IN BATTLE CASUALTIES

Major William H. Meroney (MC), U. S. Army

Early in the Korean war, as in World War II, approximately 90% of the wounded men who developed renal failure died. When a special center for the treatment of renal insufficiency was established in the combat zone of Korea, increased emphasis was placed upon the early recognition and treatment of renal failure in wounded men. Strict attention was focused on urinary output, and patients with a 24-hour urinary volume of less than 500 cc. were transferred promptly to the renal center, where specialized treatment, including artificial kidney dialysis, was available. The mortality rate for patients with renal failure fell promptly to approximately 50%, but there it remained for the duration of the war. This dreadful figure was not reduced further, even though the chemical effects of uremia responded well to methods of treatment then available. The cause of death was not always known, but it appeared not to be uremia per se.

Several pathological conditions usually were recognized in a single patient. The original trauma that led to the development of renal failure often continued to produce adverse effects at the time when uremia was at its worst stage. Additional conditions present may have been secondary effects either of the original trauma or of uremia. In this compound disorder it was quite difficult to determine the exact etiology for a specific sign or symptom or for the mechanism of death. If therapy is to be more successful it must be more specific, and this can only occur if an individual cause can be paired with an individual effect.

APPROACH TO PROBLEM

The purposes of this article are to point out the major cause of death, to describe the features of this disorder that differentiate it from uremia, and to suggest ways to lower the 50% mortality rate. The material is derived from a detailed review of the records of the patients who died at the renal center during the last six months of the war. This analysis, documented elsewhere,[1] revealed that 30% of deaths were the result of the extent, severity, or location of the initial wounds or were a direct result, such as embolism, of the nature of the wounds. In this group the early destruction of vital organs made the fatal outcome inevitable, and often initial survival was possible only because of the heroic efforts in resuscitation practiced in the forward medical installations. More than 60% of the deaths were the result of infection that was introduced with the initial trauma, and it is this group that commands our attention.

At autopsy the typical lesions of acute tubular nephrosis usually were found, and this was listed as the cause of death. The infections found at autopsy were considered to be secondary to the renal failure, although they were located in the original wounds. It has been stated that renal failure predisposes to the progression of infection, but the principal basis for this opinion appears to be the greater incidence of infection in patients with oliguria. A more likely explanation for the progression of infection during oliguria can be found in the records of the early course of the patients. The usual wounded man, who did not have prolonged oliguria, was carefully observed for signs of infection. When warning signs appeared, the best principles of surgery were employed promptly. If the general condition of the patient deteriorated, the search for hidden infection was intensified and vigorous treatment was instituted. If the patient had oliguria, however, an aura of mystery descended upon him to enshroud from view the signs and symptoms that otherwise would have provoked immediate action. Fever, unusual leukocytosis, and even classical bacterial "toxicity" did not provoke a search for infection but were obscured by conjecture as to possible effects of imbalance of electrolytes and nitrogen. The patient was not treated in accordance with the best principles of surgery, and infection progressed to an irreversible stage. The deterioration of the patient was presumed to be caused by some mysterious chemical effect of uremia, and he was transferred to the renal center, where he died of infection. This criticism is not to be interpreted as blame, for there were good reasons for the confusion. One of the factors responsible was the great emphasis placed on oliguria, fostered at the renal center, and drummed into the awareness of every doctor in the combat zone. The other principal factor was lack of knowledge of the natural course of acute uremia with and without complicating infections.

The features of post-traumatic uremia that produced symptoms during the first week could be completely, if temporarily, controlled by artificial kidney dialysis. After dialysis the patient was alert and felt well if no additional disorder was present. The chief disorder associated with uremia was infection, and the persistence of uremia-like symptoms after dialysis was highly suggestive of bacterial toxicity. At that time, when the chemical effects of uremia had been corrected, the additional diagnosis usually was apparent. However, dialysis was not usually performed until several days after the best and perhaps the only opportunity for effective treatment of infection had passed. If proper treatment of each condition was to be accomplished, the effects of uremia and sepsis had to be differentiated early in the course. The manifestations of the two conditions were strikingly similar, and, in fact, 19% of the patients transferred to the renal center with the diagnosis of uremia had sepsis but no demonstrable renal lesion. Since 80% of such patients died, there was opportunity to confirm histologically the clinical opinion that the kidneys were anatomically normal.

RENAL FAILURE AND RENAL FAILURE COMPLICATED BY SEPSIS

Clarification of certain differential diagnostic points between these conditions will be attempted by contrasting some features of a hypothetical case of pure renal failure and a case of renal failure complicated by sepsis.

Pure Renal Failure.—Consider first the patient who had acute post-traumatic renal failure but no significant infection. Typically, he suffered severe wounds with considerable hemorrhage and profound shock, from which he was resuscitated only after vigorous transfusion for several hours. There was no evidence of transfusion reaction; the wounds were débrided thoroughly as soon as the systolic blood pressure was stable at a level above 100 mm. Hg, but only 50 cc. of bloody urine was excreted during the first 24 hours. The patient was alert, afebrile and did not appear to be in toxic condition. Pain in the wounds was mild and was controlled with small, subnarcotic doses of meperidine (Demerol) hydrochloride. Because of an abdominal wound he could take nothing by mouth, and his total fluid and caloric intake consisted of a continuous intravenous infusion, running at a constant rate of ⅓ cc. per minute. Until blood chemical analysis revealed a need for a change, the infusion contained 25% glucose in water, ¼ unit regular insulin per gram of glucose, and water-soluble vitamins. On the second postwound day the patient felt and appeared essentially as before. The wounds were clean, mild hypertension was present, and an electrocardiogram was normal. Examination of the urine revealed: 24-hour volume 50 cc., grossly bloody, specific gravity 1.016, albumin 4+, numerous granular and erythrocyte casts, and sugar and acetone negative. Blood examination showed: hemoglobin level 14 gm. per 100 cc.; white blood cell count 12,000 per cubic millimeter; nonprotein nitrogen 80 mg. per 100 cc.; sodium 125 mEq. per liter; potassium 5.5 mEq. per liter; carbon dioxide level 20 mEq. per liter; calcium level 10 mg. per 100 cc.; and phosphorus (inorganic) level 4 mg. per 100 cc. The patient's condition was satisfactory.

On the third postwound day the patient was essentially the same, and the same regimen was continued. On the fourth postwound day the patient was somewhat lethargic but well oriented. He complained of thirst and slight nausea but had not vomited. Occasional periods of hiccups caused pain in the abdominal wound, and meperidine hydrochloride, 50 mg., was required four times daily. Blood pressure was 160/90 mm. Hg; the wound bandages, which were thin and loosely applied, showed a small amount of odorless, serous exudate; there were no other abnormalities. The electrocardiogram was normal. Urine examination showed: 24-hour volume 50 cc., blood tinged, specific gravity 1.010, albumin 4+, numerous granular and erythrocyte casts, and sugar and acetone negative. Blood examination showed: hemoglobin level 13 gm. per 100 cc.; white blood cell count 12,000 per cubic millimeter; nonprotein nitrogen 160 mg. per 100 cc.; sodium level 125 mEq. per liter; potassium level 6.0 mEq. per liter; carbon dioxide level 16 mEq. per liter; calcium level 8.5 mg. per 100 cc.; and phosphorus level 6.6 mg. Plans were made to dialyze the patient's blood with the artificial kidney in a day or two if diuresis did not occur. In the meantime, 100 mEq. per liter of sodium as lactate or bicarbonate were added to the infusion to modify the acidosis.

Subsequent Course: If oliguria continued and if dialysis were not performed the clinical and chemical abnormalities noted above would progress gradually. The sensorium would deteriorate as the nonprotein nitrogen concentration in the blood increased, and when the concentration reached about 250 mg. per 100 cc., the patient would become stuporous, yet tremulous and agitated. Severe hiccups and vomiting would prevent rest and invite aspiration pneumonia. Increasing thirst would provoke pleas for water in every articulate moment. Acidosis would become clinically manifest as hyperpnea. Hypocalcemia would be so severe that mild tetany would occur in spite of the acidosis. The moderate increase in serum potassium would register on the electrocardiogram as peaking and elevation of the T waves, first in the apical precordial leads, later in the limb leads, but there would be no signs or symptoms of this degree of intoxication.[2] If dialysis still were not performed, urea frost, coma, convulsions, and pericarditis would appear as the chemical imbalance reflected by the azotemia progressed further. Anemia would be significant at this stage, and moderate purpura might appear, but few patients whose blood was not dialyzed could survive to reach the stage of severe intestinal bleeding characteristic of prolonged uremia. Such a patient's blood was dialyzed about the sixth day, when symptoms became severe enough to cause suffering, to interfere with management, and to provoke complications. Earlier dialysis might have been beneficial, but the possibility of an early diuresis was great enough to justify delay of the procedure until major symptoms appeared. In a well-managed case the progression of symptoms was gradual, and there was no urgency for dialysis.

Renal Failure plus Sepsis.—Consider now a patient whose original insult appeared to be comparable but whose course was quite different. This patient was never resuscitated to the point that débridement could be completed. Continuous infusions of blood or arterenol (Nor-epinephrine) were required to maintain a systolic pressure of 100 mm. Hg, and when a needle was plugged or attention was diverted, severe hypotension recurred. On the day after being wounded this patient was feverish, thirsty, disoriented, agitated, tremulous, and nauseated and had occasional grand mal seizures. The urinary volume was only 50 cc. per 24 hours, and so blood chemistries were obtained. The nonprotein nitrogen was 60 mg. per 100 cc.; sodium level 120 mEq. per liter; potassium level 7.5 mEq. per liter; carbon dioxide level 20 mEq. per liter; calcium level 7.6 mg. per 100 cc.; phosphorus level 8 mg. per 100 cc. The white blood cell count was 25,000 per cubic millimeter with 90% polymorphonuclear neutrophils. An electrocardiogram showed peaking and elevation of all T waves, prolonged $Q\text{-}T_c$ interval, and widening and disfigurement of QRS complexes typical of potassium intoxication and hypocalcemia.[3] This patient had oliguria, azotemia, potassium intoxication, and many of the classical clinical features described in uremic patients.

---

[2] Meroney, W. H., and Herndon, R. F.: The Management of Acute Renal Insufficiency, J. A. M. A. 155: 877 (July 3) 1954.

Subsequent Course: It was not an uncommon practice in Korea to pronounce such a patient to be uremic, which was correct; to ascribe his clinical state to uremia, which was incorrect; and to transfer him to the renal center, which often was fatal. Whether the uremia was a result of tubular nephrosis or due to a temporary functional disturbance was immaterial; the clinical state was not a result of uremia; and transfer at that time was contraindicated. Artificial kidney dialysis was performed on several such patients to prevent death from potassium intoxication, but restoration of chemical balance had no effect on the clinical state. The noxious substance, if any, was not eliminated by dialysis and the deterioration continued as before. It was then apparent that the problem was not one of known chemical toxicity; however, diagnosis of extensive muscle necrosis and septicemia at that stage did not lead to successful therapy. Furthermore, the severe hyperpotassemia, which was the chief indication for dialysis, recurred rapidly after its initial correction by dialysis. The devitalized tissue that fed potassium to the plasma was still present, and during the delay, infection had spread to involve adjacent tissues. Whether or not potassium was controlled, there was increasing toxicity from bacterial contamination and, probably, dead tissue. The usual terminal events were shock and pulmonary congestion, the latter unassociated with overhydration. Postmortem examination revealed necrosis in the area of the wound, although the surface of the wound did not necessarily appear necrotic. The renal lesions found at autopsy were listed as the primary cause of death, with pulmonary congestion and infection as secondary causes.

Renal disease was not the primary cause of death, nor was it necessarily a contributory cause of death. If the immediate terminal event were potassium intoxication, failure of urinary excretion would be a contributory cause. However, potassium intoxication of equal or greater degree would have occurred if failure of excretion had resulted from hypotension or other temporary alteration in renal dynamics rather than renal disease. Potassium intoxication can be controlled if the only defect is failure of excretion, as in the first patient. The cause of uncontrollable potassium intoxication is increased loss of potassium from cells to serum during oliguria, and the rate is actually greater when oliguria is a result of functional disturbances. The hypoxia associated with hypotension causes some potassium to escape from intact cells, but this process is reversible and of secondary importance. The important source of potassium is a focus of devitalized tissue such as the incompletely débrided wound in the second patient, and the early appearance of hyperpotassemia in such a patient should prompt an intensive search for the focus.

COMMENT

Some of the potassium that escapes to the serum may be reincorporated into tissues as a carbohydrate complex when glucose is infused. Serum concentration of potassium may then rise at a slower rate and lose some of its diagnostic value as a criterion for débridement. Inorganic phosphorus, which derives from the same tissues as potassium, is less affected by glucose infusions, and the concentration in the serum can be a useful index of necrosis. In an uncomplicated case of post-traumatic renal failure serum phosphorus concentration rises slowly, 1 to 2 mg. per 100 cc. per day, in a linear fashion. If tissue necrosis is present, serial analyses show an abrupt rise, as in the second case. A convenient way to judge whether the concentration of phosphorus is higher than it should be for the duration of the oliguria is to relate it to nonprotein nitrogen. Nonprotein nitrogen concentration in serum usually rises in a linear fashion regardless of whether necrosis is present. If the nonprotein nitrogen value is divided into the phosphorus value, both in milligrams per 100 cc., a ratio is obtained that correlates roughly with the degree of necrosis. A phosphorus:nonprotein nitrogen ratio above 0.05 is highly suggestive of the presence of necrosis, if there is no other apparent reason for inordinate hyperphosphatemia.[4] Nonprotein nitrogen concentration in serum is not a good index of the degree of divitalized tissue nor does it distinguish between acute renal disease and functional disorders of renal dynamics. The degree of azotemia simply reflects the duration of oliguria and has no more significance than the diminished urinary volume, which is easier to measure.

Clinically, the two cases described had many features in common, and pathologically both had acute renal disease. However, the cause of symptoms was not the same in both. The second patient exhibited uremia-like symptoms on the first postwound day, when the nonprotein nitrogen concentration in the serum was 60 mg. per 100 cc. This syndrome did not appear in the first patient until many days had passed and the nonprotein nitrogen concentration was greater by severalfold. The time of onset of symptoms is of cardinal importance in assessing the cause of symptoms. If the duration of oliguria is unknown, it is usually correct to assume that oliguria dates from the time of injury. If this date is unknown, the duration of oliguria can be estimated accurately enough for these purposes by the nonprotein nitrogen concentration. Although considerable variation occurs, nonprotein nitrogen concentration usually rises at approximately 40 mg. per 100 cc. per day in a severely traumatized patient with oliguria. The substance that causes the symptoms of uremia is unknown, but it accumulates in the serum and is dialyzed from the serum at approximately the same rate as nonprotein nitrogen. The similarity in behavior of the two substances is limited but can be employed for clinical evaluation. Severe symptoms of acute uremia rarely appear until the nonprotein nitrogen concentration exceeds 200 mg. per 100 cc. and usually not until it is considerably higher. Other causes should be sought to explain the occurrence of uremia-like symptoms in a patient with less severe azotemia.

Imbalance of blood chemicals other than the unknown substance noted above usually produces no symptoms until the degree of imbalance is severe. Acidosis increases gradually to the point at which hyperpnea appears, usually when the serum bicarbonate concentration falls below 15 mEq. per liter. Hyperphosphatemia appears to be harmless except for its association, perhaps etiologically, with hypocalcemia. When phosphorus concentration is high, as in patients with necrotic tissue, calcium concentration is low. Frank tetany is unusual, probably because the acidosis increases the dissociation of calcium ion from the protein-bound moiety. Parestheses and less overt symptoms of hypocalcemia are most often seen when hyperpotassemia is also present, and these symptoms were formerly attributed to potassium. Because of the mutual antagonism between calcium and potassium, the symptoms of hypocalcemia are exaggerated by hyperpotassemia, and some of the unexplained convulsions in uremic patients may be related to this phenomenon. Hyperpotassemia alone does not produce symptoms until shortly before it reaches a degree sufficient to stop the heart; however, hypocalcemia will be associated with hyperpotassemia unless calcium is infused continuously. Hyponatremia usually is not severe enough to produce symptoms, although it may contribute to the symptomatology of water intoxication. Water intoxication is a common complication of uremia, although it reflects the behavior not of the disease but of the doctor. Meticulous attention to the details of fluid balance is of paramount importance in management. Distortions of the normal pattern of serum electrolytes, like the onset of symptoms, appear late and progress gradually in a well-managed and uncomplicated case of acute renal failure.

The surgeon who undertook débridement in patients such as in the second case required the courage to assume responsibility for unfavorable operative statistics and the conviction that there was no other hope for survival of the patient. Procrastination, compromise, or preoccupation with the urinary volume and consequent transfer of an undébrided patient to the renal center resulted in a fatality. If the deterrent to operation was potassium intoxication, massive infusions of calcium (100 to 300 cc. of 10% calcium gluconate solution) were effective in antagonizing the effects of potassium until surgery could be completed in some cases. If the devitalized tissue could be excised completely, the management of renal failure was relatively simple, even leisurely. The uremia-like syndrome that occurred one or two days following the onset of oliguria was not a result of uremia. It was qualitatively similar to uremia but was distinguished from it by the quantitative differences in blood chemistry and by the time of occurrence. Therapy designed to correct the manifestations of uremia was ineffective in this condition. The etiology of this syndrome in battle casualties in Korea was infection in traumatized tissues, and the only effective treatment was early and radical débridement. If the patient was a poor surgical risk and operation was deferred, further deterioration rather than improvement was the rule.

CLINICAL NOTES

FOOTBALL HEMATURIA

Alex W. Boone, M.D.
Earl Haltiwanger, M.D.
and
Robert L. Chambers, B.S. Ed., Durham, N. C.

The football player has hematuria. Player, parents, and coach want to know: Is it serious? Will there be permanent damage? When may he safely play again? Many physicians face these questions each fall and find it difficult to formulate a satisfactory answer. Ultraconservatism may evoke critical comment from ardent team supporters who want the star player back in action. On the other hand, the parents naturally fear that the physician has submitted to pressure if their son returns to active play shortly after having had hematuria. It is known that exercise decreases urinary volume, diminishes renal plasma flow, and decreases chloride concentration.[1] It is also well established that albuminuria may follow exercise.[2] Amelar and Solomon [3] have reported microscopic hematuria in 73% of boxers immediately after a bout; however, information is not available on incidence and significance of hematuria in athletes participating in strenuous exercise and sustaining repeated trauma for several consecutive months. This study was made to obtain data on these points.

METHOD

The members of the varsity football team of a major university were subjects for the study. Urine was secured from each man the day he reported for training. A specimen was then obtained on each of three consecutive days. Through the remainder of the season urine was collected each Wednesday after practice and each Saturday after the football game. Three postgame collections were missed because of distance. Urine was collected within 30 minutes after each of seven games. Occasional specimens were missed either because of injury or because an individual could not void. Player interest and cooperation were excellent. The fresh urine was examined, a record being made of the color, turbidity, pH, specific gravity, albumin level, sugar level, and results of microscopic examination. A total of 874 urine specimens were collected from 58 individual players during the season. Men dropped from the squad, out of action because of prolonged injury, or failing to make the traveling team reduced the number of regular biweekly urine contributors to 37.

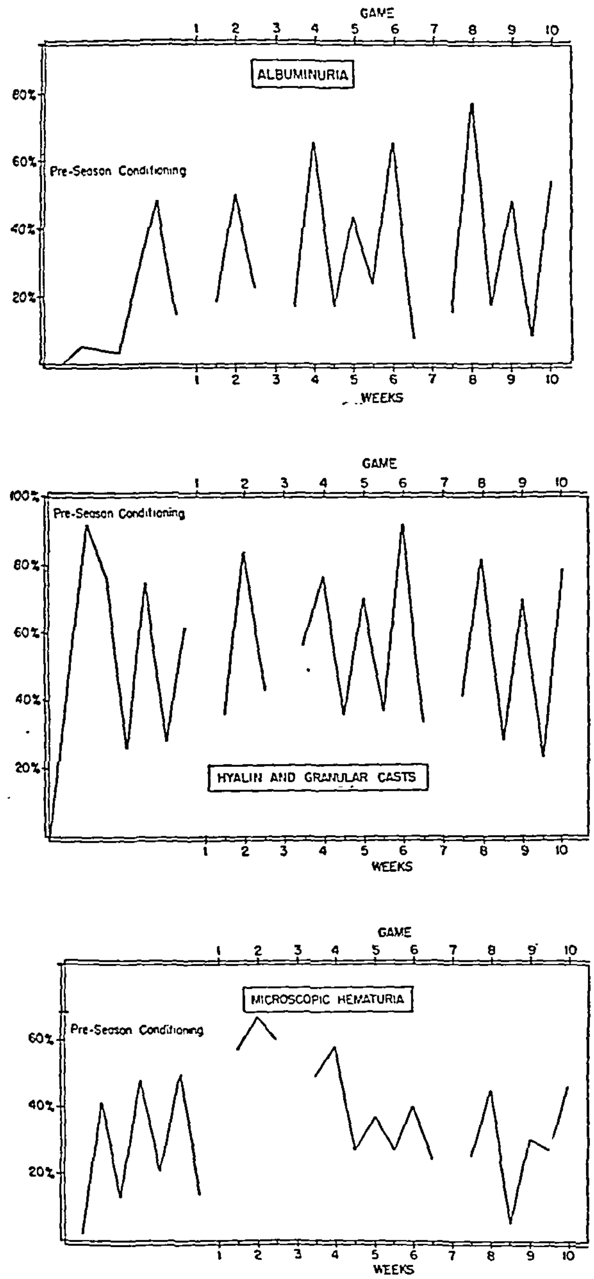
RESULTS

Except for one man with an occasional red blood cell per microscopic field, each man's urine was normal when he reported to training camp. The exercises of the preliminary conditioning program produced albuminuria, casts, and microscopic hematuria in many of the players (see chart). With the beginning of body contact work, urinary abnormalities increased. Throughout the remainder of the season the percentage of abnormal urine specimens reached a peak after Saturday games. There was usually a drop in this percentage at midweek. One player had microscopic hematuria in 19 of 24 specimens examined. All of the others bled intermittently, the next highest rate being hematuria in 11 of 22 specimens. Hematuria sufficient to grossly discolor the urine was noted in six men. None of these men withdrew from competition, and all promptly reverted to "football normal" within three to four days. No man had gross hematuria on more than one occasion. The rapidity with which the urine returned to normal was remarkable. A specimen obtained Wednesday afternoon following a hard scrimmage would often be slightly cloudy, contain two to five red blood cells per high-power field, occasional leukocytes, and a moderate number of hyaline and granular casts. If this same player sat on the bench during Saturday's game his postgame urine specimen was usually absolutely normal. The following cases illustrate patterns of hematuria observed during the 1954 season.



Urinary findings during the preseason conditioning period and the regular season in members of a varsity football team.

REPORT OF CASES

CASE 1.—Normal initial urine was followed by microscopic hematuria in three out of seven specimens. Gross bleeding on one occasion decreased to microscopic hematuria three days later. Blood was noted microscopically in 5 of the next 12 urine specimens.

CASE 2.—Normal initial urine was followed by microscopic hematuria in 6 out of 13 specimens. Gross bleeding was followed by a clear urine microscopically four days later. Microscopic hematuria was noted in one of the next seven specimens.

CASE 3.—Normal initial urine was followed by microscopic hematuria in 16 out of 21 specimens. Gross bleeding on one occasion was followed by microscopic hematuria in each of the last two specimens.

CASE 4.—Normal initial urine was followed by microscopic hematuria in 5 out of 14 specimens. Gross hematuria gradually subsided for three days. There was microscopic hematuria in three of last five specimens.

CASE 5.—Normal initial urine was followed by microscopic hematuria in 6 out of 17 specimens. Gross bleeding was noted for one day. Microscopic hematuria was noted in two of remaining three specimens.

CASE 6.—Normal initial urine was followed by microscopic hematuria in one out of eight specimens. Gross bleeding was noted on one day. Microscopic hematuria was then noted in four of the next seven specimens. This player then became inactive because of other injuries.

SUMMARY

It has been found that hematuria frequently accompanies participation in football. Microscopic bleeding may accompany the strenuous physical exertion of preseason conditioning exercises. A moderate increase in the number of players with microscopic hematuria occurs with body contact drills. A definite peak in the hematuria incidence occurs after each football game. There is no increase in the postgame hematuria rate as the season progresses. Gross hematuria was noted in the urine of 6 of 37 men followed closely throughout the football season in 1954. Both the gross and microscopic bleeding cleared promptly with rest. We found no reason to restrict activity because of microscopic hematuria. In fact, if such had been carried out the entire team eventually would have been benched, for no player failed to develop microscopic hematuria. Similarly, when a single episode of gross hematuria subsided to microscopic levels within 24 to 72 hours, there seemed to be no harm in resumption of full activity.

SEVERE ADRENOCORTICAL INSUFFICIENCY FOLLOWING JOINT MANIPULATION

REPORT OF PATIENT RECEIVING CORTISONE ORALLY

Edward E. Harnagel, M.D.
and
Warren G. Kramer, M.D., Los Angeles

The widespread use of adrenal steroids as therapeutic agents has demonstrated that these hormones, if given long enough in sufficient dosage, consistently induce adrenal atrophy and suppress pituitary and adrenocortical function.[1] Less well known, perhaps, is that adrenocortical and pituitary function may also be impaired for some time after corticotropin has been administered.[2] Changes may persist for as long as six months after therapy has been stopped. Eventually, however, function returns to normal, and the interlude of hormone-induced adrenocortical insufficiency is usually not of serious importance. If an episode of stress should supervene at this time, however, the consequences may be grave. To maintain homeostasis under stress, increased amounts of adrenocortical hormones are needed.[3] A normal adrenal cortex responds with a manifold increase in hormonal output [4]; the adrenal cortex that has been suppressed by prolonged administration of exogenous adrenal hormones cannot always respond adequately. Fraser and others,[5] and Lewis and others [6] have reported cases of fatal adrenocortical insufficiency precipitated by surgical procedures in patients who have received cortisone for prolonged periods. Salassa and his colleagues have reported two fatal cases; one of these was of particular interest because the stress that precipitated the fatal outcome was a minor surgical procedure, a bunionectomy, and because oral therapy with cortisone had been discontinued four and a half months prior to surgery and intra-articular administration of hydrocortisone 15 days prior to surgery.[7] We wish to report a case of severe and nearly fatal adrenocortical insufficiency that occurred in a patient who had been receiving cortisone orally after manipulation of a knee joint with the patient under thiopental (Pentothal) anesthesia.

REPORT OF A CASE

A white man was first seen in 1946 at the age of 13 years because of low back pain and stiffness of approximately 3 years' duration. For about two years his parents had noticed that he would limp on his left leg when tired. Examination at this time revealed tenderness over the lumbosacral area and a moderate limitation of flexion, abduction, and external rotation of both hips. X-rays of the pelvis revealed some widening and fuzziness of the sacroiliac joint margins. In the next six months he developed persistent pain, stiffness, and swelling of the knees, ankles, and feet. One year later the clinical picture was typical of severe rheumatoid spondylitis with peripheral joint involvement. At this time, x-rays revealed that the sacroiliac joints were obliterated and that the hip joints had become markedly narrowed. Despite intensive physical therapy and a host of medicaments, including salicylates, streptococcic vaccine, vitamins, gold salts, and corticotropin, progression of the disease was not checked. By 1950 the spine was rigid except for approximately 30 degrees of flexion-extension motion of the neck; the hip, knee, ankle, tarsal and metatarsal joints were badly damaged. The patient could wiggle his toes a bit, but otherwise the lower extremities were completely ankylosed.

In January and February, 1951, cup arthroplasties were performed on the hips. The arthroplasty on the left hip was revised in December, 1951, because of bony proliferation around the joint. In March, 1953, wedge osteotomies of both ankles were done to correct plantar flexion deformities of the feet. By November, 1953, the patient was able to walk fairly well with the aid of crutches, but, because of ankylosis of knees and ankles, he found it difficult to climb steps. In an attempt to improve ambulation, an arthroplasty of the left knee was performed in November, 1953, with the use of a fascia lata transplant. The knee remained quite painful postoperatively for weeks, and development of motion was slow despite intensive physical therapy. Manipulations of the knee joint were done in December, 1953, and again in January, 1954; on both occasions 25 mg. of hydrocortisone acetate was injected into the joint. Little improvement in motion or relief of pain resulted from these procedures. It should be emphasized that the patient tolerated these manipulations and the previously described major surgical procedures very well.

On Jan. 16, 1954, oral therapy with cortisone acetate was started in doses of 75 mg. daily for seven days; the dose was then reduced to 62.5 mg. daily. Though this medication did not improve the range of motion, the patient felt very definitely that it relieved the pain and stiffness to a substantial degree; it was, therefore, continued. On Feb. 16, 1954, at which time the patient had received approximately 1.9 gm. of cortisone, another manipulation of the left knee was performed with the patient under thiopental anesthesia. Breakfast and cortisone were withheld on this morning. Because of a heavy surgical schedule, the procedure was deferred until early afternoon. The period of anesthesia was approximately five minutes, and the actual manipulation required only a minute. Recovery from the anesthesia was somewhat slow. At 6 p. m. it was noted that the patient was awake and alert but nauseated. He therefore omitted his evening meal and his evening dose of cortisone. At midnight he talked to the ward nurse and apparently seemed to be all right. At 2 a. m. Feb. 17, the attention of the nurse was drawn to the patient because of his stertorous respirations. Examination revealed that he was deeply comatose, very cyanotic, and drenched with cold sweat. There was a conjugate deviation of the eyes upward and to the right; pulse rate was 140 per minute and was weak and thready. Blood pressure was unobtainable by auscultation; by palpation, systolic pressure was judged to be approximately 90 mm. Hg. Hoffman's signs were elicited bilaterally. Since the toe joints were ankylosed, plantar responses could not be tested. Heart tones were loud, and rhythm was regular; the lung fields were clear to auscultation. Total eosinophil count at 8 a. m. was zero; at 2 p. m., 240 per cubic millimeter;

From the medical and surgical services of the Los Angeles Orthopedic Hospital.

and at 4 p. m., 70. Analysis of serum on Feb. 17 and Feb. 18 showed sodium 149 mEq. per liter, potassium 4.2 mEq. per liter, and chloride 111 mEq. per liter. Carbon dioxide content on Feb. 17 was 22 mEq. per liter (normal value 26-28 mEq. per liter). The 17-ketosteroid value on Feb. 22 was 2.2 mg.

Treatment.—Oxygen was given by nasal catheter. An infusion of 5% glucose in isotonic sodium chloride containing 4 cc. of 0.2% solution of levarterenol bitartrate (Levophed) per liter was run continuously for 36 hours. Also, an infusion of 5% glucose in distilled water containing 80 U. S. P. units of corticotropin per liter was started in the other arm at 4 a. m., Feb. 17, and allowed to run very slowly, so that approximately 80 units were administered in 24 hours. This solution was given for four days without stopping. Since a preparation of cortisone to be given intramuscularly was not immediately available, four 25 mg. cortisone tablets were crushed and put in the rectum. Four hours later when the preparation for parenteral use was obtained, 200 mg. was given intramuscularly, and 100 mg. was given daily for the next five days. Ten cubic centimeters of adrenal cortical extract (Eschatin) was given on the first day of treatment. Oxytetracycline, 500 mg. intravenously, and penicillin, 600,000 units intramuscularly, were given daily for six days.

Course.—For 24 hours the patient seemed moribund. Cyanosis was slow to disappear, even with oxygen therapy. His temperature rose to 106.8 F, and the blood pressure was unobtainable by auscultation. The pulse remained weak and varied from 140 to 160 per minute. Twitchings and muscle spasms of the jaws, arms, and legs developed, which at times suggested decerebrate rigidity. These were not modified in any way by the intravenous administration of calcium gluconate. Then, over a period of 12 hours, the muscular phenomena stopped, the temperature dropped to 101 F, and the blood pressure slowly rose to 90/70 mm. Hg. The patient gradually regained consciousness. No alterations in intellect or personality were observed, and there were no detectable neurological residual effects. He made a rapid recovery in well-being and strength. At the end of a week he was up in a wheel chair and, so far as we could determine, was none the worse for his experience.

COMMENT

The following data, in our opinion, strongly suggest that the profound shock noted in this case was due to adrenocortical insufficiency: 1. The patient had received 1.9 gm. of cortisone in one month; this amount is more than sufficient to produce adrenal atrophy and suppress pituitary and adrenal function. 2. He received no cortisone for 18 hours prior to the manipulation and for 30 hours prior to the onset of shock. 3. Normal eosinophil counts were observed on two occasions several hours after intravenous therapy with corticotropin was started. 4. The level of the urinary 17-ketosteroids was very low, even after four days of intense adrenocortical stimulation by corticotropin intravenously.

The neurological signs observed in this patient are somewhat unusual in adrenal crises and have suggested to several observers the possibility of fat embolism or thromboembolism. It is our feeling, however, that the prompt and complete recovery without neurological deficit makes occurrence of a cerebrovascular accident unlikely. It should be recalled that the patient was very cyanotic at the time of shock and this cyanosis was slow in disappearing. We believe the muscle twitchings and spasms can perhaps be attributed to cerebral anoxia.[8]

Obvious errors in management of this case were withholding cortisone before manipulation and failing to give it promptly postoperatively by the intramuscular route when it became apparent that the patient could not take it orally (hydrocortisone preparations to be given intravenously were not available at this time). These errors were, in part, due to the false assumption that such a minor procedure as joint manipulation, done with the patient under thiopental anesthesia, would not constitute a serious stress.

Thorn and his colleagues have remarked that adrenal crises are more common in those who have received cortisone orally.[9] This is due to its short period of activity. It reaches its peak of effect approximately 4 hours after ingestion, and, after 12 hours, its action is largely dissipated. It cannot, therefore, be expected to provide a sustained protection against adrenocortical insufficiency throughout the course of a surgical procedure, particularly when medicaments to be given orally must be withheld postoperatively for many hours. Anorexia, nausea, and vomiting, furthermore, are common symptoms in many conditions of stress and frequently preclude the continuance of oral therapy with any medicament. The patient who has been receiving cortisone orally for instance, may not be able to continue taking it at a time when he greatly needs it. This would, of course, invite disastrous occurrences as described above. We believe that any patient receiving cortisone orally upon whom even minor surgical or dental procedures are contemplated should instead be given a preparation for intramuscular use two or three days prior to surgery. Furthermore, unless the surgical procedure is a very minor one, supplementary amounts of adrenal hormones, as outlined by Salassa and others, should be given preoperatively and postoperatively.[7] Certain precautionary measures may enable the patient to avoid an adrenal crisis. Prolonged fasting of such patients should be avoided. If parenteral administration of fluids is required, 5% glucose in isotonic sodium chloride should be used, rather than 5% glucose in distilled water. Morphine and its derivatives should be used sparingly, if at all. Patients should be watched very closely, particularly during the first 24 hours after surgery; temperature, blood pressure, and pulse rate should be recorded hourly during this period.[7] If an injury or serious illness occurs in a patient taking cortisone orally and if there is any doubt that he will be able to continue taking the medicament orally, it should be given by the intramuscular or intravenous route without delay.

Bronchography.—Bronchiectasis may be a localized disease involving only a portion of a single lung segment or subsegment. Localized bronchiectatic dilatations often fail to cast shadows on routine chest films. At other times the localized bronchial dilatations become filled with fluid and surrounded by zones of pneumonitis, producing circumscribed, rounded shadows on the usual chest films. These nodular densities may simulate tumors of the lung. The studies carried out for the evaluation of circumscribed pulmonary densities frequently do not include bronchography. Bronchography can reveal graphically that pulmonary "coin" lesions noted on ordinary chest roentgenograms may be manifestations of localized bronchiectasis. This simple procedure may clarify the diagnosis and indicate the treatment required. Many unnecessary exploratory thoracotomies may thereby be obviated.—B. Schwartz, M.D., and H. L. Katz, M.D., Localized Bronchiectasis Simulating Pulmonary Neoplasms, *Annals of Internal Medicine,* July, 1955.

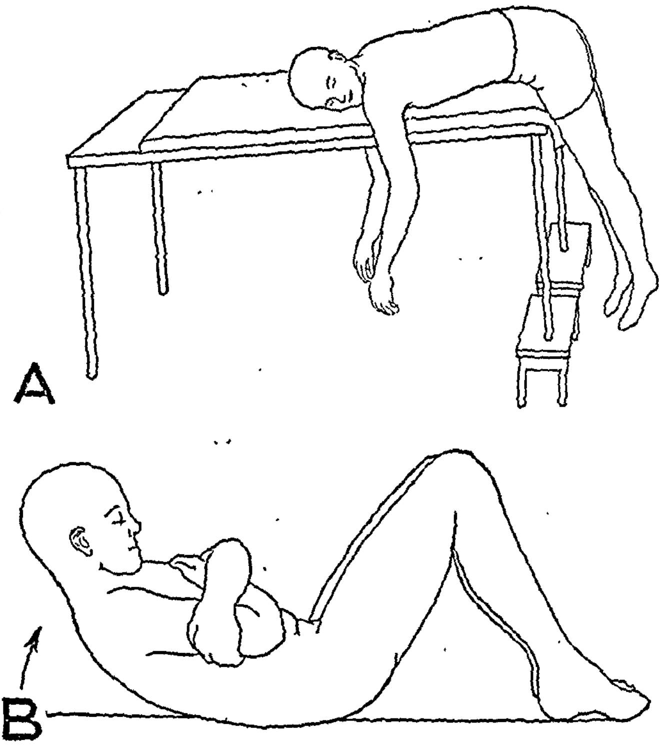
ACUTE LOW BACK PAIN

Robert P. Kelly, M.D.
and
J. Trimble Johnson, M.D., Emory University, Ga.

Orthograde posture in man is possible only with the cervical and lumbar curves of the spine steadied by the powerful sacrospinalis muscle groups. In man's transition from the more primitive postures only the rectus abdominis muscles remain to flex the lumbar spine and counter those forces tending toward further extension. In present-day sedentary activities, the abdominal muscles are seldom used for function other than to retain abdominal viscera; yet in sitting, in standing, and in work and play the lumbar spine and lumbosacral joint are constantly subjected to hyperextension. Williams,[1] Thieme,[2] and others point to hyperextension as one of the important precipitating factors in lumbar breakdown in man, including protruded intervertebral disk, spondylolisthesis, and the poorly understood syndrome often called "lumbago," "sacroiliac strain," or, for want of a better term, the lumbosacral syndrome. Of the latter group we have had particularly encouraging results with conservative treatment and feel its clinical recognition and simplicity of treatment demand emphasis.

These patients, predominantly in the fourth through the sixth decades of life, give a fairly consistent history of acute low back pain, described as a "catch" in the region of the lumbosacral joint and usually initiated by an unusual torsion or hyperextension of the lower spine. While the precipitating effort may be trivial, the onset of symptoms is frequently dramatic in suddenness and severity. It may follow the insult by several hours. Once the attack is started, slight movement may initiate paroxysms of excruciating pain. This is accompanied by spasm of the back muscles and may radiate out across one buttock. It is aggravated by prolonged sitting, standing, and recumbency; and a general attitude of flexion affords the greatest relief. Greatest pain may be experienced when, after prolonged sitting, the patient moves to resume the erect posture. This latter we consider one of the prime characteristics of the clinical picture.

As the patient gives the history, he sits squarely on his buttocks or shifts from side to side. This is in contrast to patients with the protruded intervertebral disk syndrome, in which case the weight often is thrust to the opposite buttock. On standing, there is usually spasm of the lumbar erector spinae muscles. The crest of the ilium may be elevated on the side of pain with forward rotation of the pelvis on the same side. There is marked limitation in forward and lateral flexion, with the pain exacerbated by flexion away from the side of pain. Point tenderness is found over one or both of the lumbosacral joints. The deep tendon reflexes of the lower extremities are normal, and there are no sensory changes. X-rays of the lumbar spine and lumbosacral joint are usually read as negative. Occasionally a slight narrowing of the lumbosacral or L_4-L_5 disk space is seen, without sciatic nerve root compression on myelography. To us the clinical picture is in sharp contradistinction to that of the protruded intervertebral disk syndrome. After several days of persistent back pain, victims of the lumbosacral syndrome may develop leg pain that assumes a variable importance. Nonetheless, this leg pain subsides rapidly in response to the measures here advocated. The clinical picture is quite characteristic, although back pain from prostatic disease, multiple myeloma, and metastatic tumor of the spine sometimes resembles it.



A, hanging position. *B*, Williams abdominal muscle exercise.

Initial treatment should be aimed at relief of muscle spasm. In most cases this can be accomplished by a maneuver we call "hanging" (see figure, *A*). The diagram shows the proper attitude of the patient over a table, elevated at one end to prevent the subject from sliding backwards and padded to protect the inguinal crease and genitals. The desired elevation can usually be obtained by placing two soft-drink crates under each leg of the elevated end, but this will vary slightly with the body build of the patient. An ordinary examining table with both legs of one end supported by an examining room foot stool constitutes the ideal "hanging" apparatus. "Hanging" should be maintained for at least 10 minutes and should be repeated as often as necessary to relieve pain—in some cases every hour. Once the acute back pain and muscle spasm have subsided, it is no longer of value. With unusually severe symptoms, hospitalization is desirable so that skeletal muscle relaxants can be given in addition to supervision and encouragement of the exercises. For a relaxant we have used a slowly absorbed intramuscular preparation of tubocurarine chloride pen-

[1] Williams, P. C.: The Conservative Management of Lesions of the Lumbosacral Spine, the American Academy of Orthopaedic Surgeons Instructional Course Lectures, Ann Arbor, Mich., J. W. Edwards, 1953, vol. 10, pp. 90-121.

[2] Thieme, F. P.: Lumbar Breakdown Caused by Erect Posture in Man, Anthropological Papers No. 4, Michigan University Museum of Anthropology, Ann Arbor, Mich., University of Michigan Press, 1950.

tahydrate (Tubadil), which is supplied in concentrations of 25 mg. per cubic centimeter. The average daily maintenance dose has been 1 cc.

Once the patient is convinced of pain relief with the "hanging" maneuver, the abdominal muscle exercise must be started. A multitude of daily gymnastics discourage the average victim. We have emphasized only the exercise shown and found the results quite adequate (see figure, *B*). This exercise will be recognized as one for the abdominal muscles as advocated by Williams. It is recommended that the exercise be done once a day after arising from bed in the morning. The floor affords a more uniform platform than the bed, and flexion of the knees is essential. Thirty repetitions of the exercise are done in groups of 10 each. A rest of one or two minutes is taken between each group of 10. The initial effort, as will be described, is minimal, and there is progressive effort with each successive group of 10 repetitions. On the first 10, the neck is merely flexed to bring the chin as near to the sternum as possible. In the successive groups this likewise constitutes the initiating movement of the exercise. Added to it in the second group of 10 is an effort to raise the shoulders slightly from the floor. With the third group of 10 this effort is extended so that the shoulders are elevated as far toward the sitting position as possible. The rhythm of the exercise is slow and deliberate. Lurching movements should be discouraged. As the patient's capacity to perform the exercise improves, the starting effort might be as vigorous as the effort made at first in the final group of 10. In most cases this exercise, persisted in daily even after complete disappearance of symptoms, is sufficient to maintain the desired tone of the rectus abdominis muscles.

Adjuncts to the abdominal muscle exercises are instructions in daily postural attitudes that avoid lordosis of the lumbar spine, as well as weight reduction in the obese patients. There will be some cases in which the exercise will not be feasible due to one cause or another. Here the Williams lumbar flexion brace has been found useful, but should be avoided when the proper rectus muscle tone can be developed. There still remains a small group of patients who fall between the pattern of sciatic nerve root compression and the lumbosacral syndrome, e. g., those with sciatic radiation of pain without neurological derangement and with negative myelograms. Some can avoid surgery by continuous and wholehearted efforts at the measures just described. Others will eventually come to spinal fusion. However, we feel the former measures should always come first and, if vigorously emphasized, will reduce the number of patients with low back pain who are subjected to surgery or who are diagnosed as psychoneurotic and who resort commonly to treatment by the cults.

SUMMARY

A clinical entity of acute low back pain that we consider common and demanding of emphasis can be treated effectively by the family doctor. By shouldering this responsibility he will save the patient from the hazards of the cultist and unnecessary consultation with specialists.

BASILAR RALES IN MYOCARDIAL INFARCTION

Jack M. Kaufman, M.D.
and
Nancy T. Caputo, M.D., Detroit

The typical case of myocardial infarction, with severe chest pain, drop in blood pressure, and cardiac electrocardiographic findings is a textbook diagnosis. Further examination in such cases is usually not necessary. It is the atypical case of infarction that offers a challenge in diagnosis. By chance, one of us (J. M. K.) had occasion to examine four patients with atypical but similar cases of myocardial infarction. The similarity lay in the fact that none of the patients described the usual chest pain, but all had midabdominal pain, drop in blood pressure, and left-sided basilar pulmonary rales.

REPORT OF CASES

Case 1.—A 46-year-old white man complained of nausea, vomiting, diarrhea, and mild midabdominal pain. Physical examination revealed a blood pressure of 90/60 mm. Hg that at first was attributed to peripheral vascular collapse; however, there were also profuse subcrepitant basilar rales on the left that could not be explained on this basis. The patient was hospitalized when he failed to respond to treatment for a gastrointestinal upset. His symptoms abated in the hospital, but the hypotension persisted. An electrocardiogram showed a typical posterior myocardial infarction. He made an uneventful recovery.

Case 2.—A 63-year-old white woman, with complaints of mild epigastric pain, nausea, and vomiting, was seen one week after the patient in case 1. Her symptoms were unimpressive, but physical examination revealed many subcrepitant inspiratory rales at the base of the left lung, with an occasional rale at the base of the right lung and a blood pressure of 100/70 mm. Hg. With case 1 in mind, the patient was hospitalized as an emergency patient. An electrocardiogram showed a posterolateral myocardial infarction. The rales persisted for seven days. On the seventh day the patient was found dead in bed by a nurse on a routine ward check. Postmortem examination showed an extensive posterolateral infarction. Grossly, both lungs appeared edematous, the left more so than the right.

Case 3.—About a month after seeing the patients in cases 1 and 2 we were called to see an elderly couple who were both complaining of supposed "food poisoning" that followed the ingestion of potato salad at a picnic. The symptoms consisted of nausea, vomiting, and mild abdominal distress; however, the man had a blood pressure of 98/60 mm. Hg and many basilar pulmonary rales on the left. An electrocardiogram taken at home revealed a posterior myocardial infarction. He recovered completely with routine care at home.

Case 4.—A 69-year-old Negro man complained of moderately severe epigastric pain, nausea, and vomiting. His history revealed a peptic ulcer with frequent acute exacerbations. The attending physician, not satisfied with the patient's response to ulcer management, requested consultation. The only abnormal physical finding was that of left-sided pulmonary basilar rales. An electrocardiogram showed an anterior myocardial infarction. He was discharged in three weeks after a good response to routine care.

The fact that diagnosis was made in these four cases because of the suspicious finding of left-sided basilar rales prompted us to reexamine 200 cases of myocardial infarction. Seventy-five patients were followed personally, and 125 cases were reviewed from the records of Harper

---

From [illegible] Department of [illegible]y, Harper Hospital.

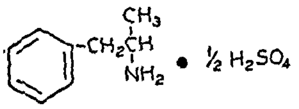
plication. Results of studies with experimental animals indicate that it has a low toxicity and exhibits about one-half the antispasmodic activity of atropine. As with other cycloplegic-mydriatic agents, caution should be observed in patients with high intraocular pressure.

Dosage.—Cyclopentolate hydrochloride is administered only in the form of ophthalmic solutions for instillation into the conjunctival sac. For refraction in Caucasians, a dose of two drops of a 0.5% solution in each eye (each drop instilled at 5 minute intervals) for adults produces maximal cycloplegia in 30 to 60 minutes. Complete recovery occurs within 24 hours. The administration of one or two drops of 1 to 2% pilocarpine nitrate reduces recovery time to 6 hours or less. In deeply pigmented eyes of dark-skinned persons, satisfactory cycloplegia may be obtained with the 0.5% solution in about two-thirds of the cases. A 1% solution usually produces maximal cycloplegia in Negro patients; instillation of a 2% solution results in return of reading ability in 6 hours. For children, pretreatment with cyclopentolate on the day prior to examination is not usually necessary. Normally one or two drops of a 0.5 or 1% solution is instilled in each eye at the time of refraction, followed 10 minutes later by a second such application. This regime will produce satisfactory cycloplegia in all but the most refractory cases. If pretreatment in such individuals seems desirable, one or two drops of 1% cyclopentolate may be instilled the evening prior to examination. Only in children with extremely dark irises has pretreatment with atropine been occasionally necessary.

For producing paralysis of the sphincter to correct spasm caused by inflammation, one or two drops of a 0.5% solution is instilled every 6 to 8 hours. For breaking or preventing lenticular adhesions secondary to infections, one or two drops of a 0.5% solution is instilled, followed in 6 hours by the instillation of 2% pilocarpine nitrate. Such alternate treatment should be carried out every 24 hours.

Schieffelin & Company cooperated by furnishing scientific data to aid in the evaluation of cyclopentolate hydrochloride.

Dextro Amphetamine Sulfate, U. S. P.—$(C_9H_{13}N)_2 \cdot H_2SO_4$.—M.W. 368.50.—*d*-1-Phenyl-2-aminopropane sulfate.—The dextrorotatory isomer of amphetamine sulfate.—The structural formula of dextro amphetamine sulfate may be represented as follows:



Actions and Uses.—Dextro amphetamine sulfate has the same actions and uses as the racemic compound, amphetamine sulfate, but exerts a predominantly greater stimulating effect on the central nervous system. Because of its relatively weak peripheral activity, it is generally regarded as less toxic than previously introduced sympathomimetic amines that are commonly employed clinically. Thus, it seldom gives rise to undesirable side-effects such as mydriasis, tremor, tachycardia, and changes in blood pressure. Dextro amphetamine sulfate, therefore, is useful by oral administration for the treatment of narcolepsy and postencephalitic parkinsonism, and as an adjunct in the management of acute and chronic alcoholism and alcoholic psychoses of recent origin. It is employed also for the symptomatic treatment of depressive states, especially to elevate the mood in early, mild, psychogenic depression characterized by apathy and psychomotor retardation and, to a variable or lesser extent, in psychoneuroses, and in severe depressions involving certain major psychopathic conditions of institutionalized patients. The drug also may be used as a stimulant in the management of certain behavior problems of children, but it is not useful in schizophrenics and has an unfavorable effect on children with psychopathic personalities. The appetite-depressant effect of the drug also is useful as an adjunct in the dietary management of obesity.

Dextro amphetamine sulfate should not be employed as a stimulant by normal persons to mask fatigue caused by physical exertion or overwork. It should be used with caution in patients hypersensitive to sympathomimetic amines, those with coronary or cardiovascular disease, and those with severe hypertension. It is contraindicated in the presence of hyperexcitability and agitated prepsychotic states. If administered too late in the day, the drug may interfere with sleep.

Dosage.—Dextro amphetamine sulfate is administered orally. In the treatment of depressive states or alcoholism, the usual daily dosage ranges from 5 to 15 mg., administered as ordinary tablet or liquid medication in two or three doses at intervals of either 4 or 6 hours. The initial dose should be given on awakening so as to complete the total daily amount early in the day. For narcolepsy, the usual daily dosage for adults ranges from 10 to 50 mg., preferably in divided amounts; for postencephalitic parkinsonism, the daily dosage is usually 10 to 25 mg., also in divided amounts. To control appetite in obesity, the usual daily dosage for adults is 15 to 30 mg. in three divided doses, taken 30 to 60 minutes before meals. Light sleepers may take the final dose early (4 p. m.).

For children with behavior problems, the suggested dosage is 5 to 10 mg. in the morning and 2.5 to 5 mg. at noon. In all cases, the dosage should be individualized; it is advisable to begin with an initial dose of 5 mg. for adults or 2.5 mg. for children, followed by either one or two additional doses of the same amount. Dosage then can be increased to obtain the desired effect; the initial daily dose may be increased at first, leaving the repeated doses at the original level so that the major quantity is taken during the first half of the day. If necessary, the later doses may be equalized gradually to provide a uniform action.

A capsule containing 10 or 15 mg. of dextro amphetamine incorporated into variably coated pellets that afford continuous release of the drug over a period of 8 to 10 hours, thus prolonging the therapeutic effect for 10 to 12 hours, may be administered once daily in the morning to adults in place of ordinary oral medication in divided amounts.

Smith, Kline & French Laboratories cooperated by furnishing scientific data to aid in the evaluation of dextro amphetamine sulfate.

Erythromycin Ethyl Carbonate.—Erythromycin ethyl carbonate is the ethyl carbonate ester of erythromycin, an antibacterial substance produced by the growth of

Streptomyces erythreus Waksman. The structural formula of erythromycin ethyl carbonate has not been established.

Actions and Uses.—Erthromycin ethyl carbonate, a salt of erythromycin, shares the actions and uses of the parent antibiotic. (See New and Nonofficial Remedies 1955, under the monograph on erythromycin.) The ethyl carbonate salt is suitable for the extemporaneous preparation of flavored suspensions of the drug for oral administration.

Dosage.—Erythromycin ethyl carbonate is administered orally in doses expressed in terms of erythromycin base. For adults, a dose equivalent to 200 mg. of erythromycin every 4 to 6 hours is considered adequate. The optimal dosage for children has not been finally determined, but a dose equivalent to 5 mg. of erythromycin per pound (about 11 mg. per kilogram) of body weight administered every 6 hours is considered reasonable.

Eli Lilly & Company cooperated by furnishing scientific data to aid in the evaluation of erythromycin ethyl carbonate.

Erythromycin Glucoheptonate.—Erythromycin glucoheptonate is the glucoheptonate salt of erythromycin, an antibacterial substance produced by the growth of Streptomyces erythreus Waksman. The structural formula of erythromycin glucoheptonate has not been established.

Actions and Uses.—Erythromycin glucoheptonate has the same action and uses as the base except that it is primarily suited for intravenous injection. (See New and Nonoffiicial Remedies 1955, under the monograph on erythromycin.) Parenteral administration is indicated for erythromycin-susceptible infections in patients who are unconscious, who are vomiting, or who are unable for any other reason to take the drug orally. In such cases oral medication with the base or other salts should be resumed as soon as the patient can ingest and retain it.

Dosage.—For intravenous injection, an initial solution should be prepared by completely dissolving the equivalent of 0.25 gm. of erythromycin base in not less than 10 cc. of water for injection, U. S. P. This solution retains its potency for 7 days if kept in a refrigerator. *Saline or other diluent should not be employed for making the initial solution in order to avoid gel formation or slow and incomplete solution of the drug.*

For adults, the initial solution should be added to 250 to 500 cc. of isotonic sodium chloride solution or 5% dextrose solution and administered by slow intravenous infusion for 20 to 60 minutes. This dose (0.25 gm. equivalent to the base) may be repeated every 6 hours. A continuous slow infusion, administering the equivalent of 1 to 2 gm. of the base over a 24 hour period, may be employed as an alternate method.

For children, the initial solution is diluted as for adults but is administered in doses calculated on the basis of the equivalent of 5 mg. of the base per pound (about 11 mg. per kilogram) of body weight every 6 hours. Although the initial solution may be used for intravenous injection over a 5 minute period without severe reactions, this is not recommended because of nausea, vomiting, or pain along the vein; thrombosis has occurred in some instances.

Eli Lilly & Company cooperated by furnishing scientific data to aid in the evaluation of erythromycin glucoheptonate.

Erythromycin Lactobionate.—Erythromycin lactobionate is the lactobionate salt of erythromycin, an antibacterial substance produced by the growth of Streptomyces erythreus Waksman. The structural formula of erythromycin lactobionate has not been established.

Actions and Uses.—Erythromycin lactobionate, a water-soluble salt of erythromycin suitable for intravenous or intramuscular injection, has the same actions and uses as the base. (See New and Nonofficial Remedies 1955, under monograph on erythromycin.) Injection of the drug is indicated in patients unable to tolerate oral medication or in whom high blood levels are necessary to control severe erythromycin-susceptible infections resistant to other antibiotics. Oral therapy with erythromycin base or other salts should be resumed as soon as this becomes feasible. Erythromycin lactobionate, injected properly, has not been reported to produce thrombophlebitis following intravenous administration or tissue damage following intramuscular injection, but moderate to severe pain usually accompanies the latter.

Dosage.—Erythromycin lactobionate is administered either intravenously or intramuscularly, preferably by the former route to avoid pain produced by the latter route. Dosage is expressed in terms of erythromycin base. The usual dosage for children and adults is 1 to 2 mg. per pound (2.2 to 4.4 mg. per kilogram) of body weight either intravenously or intramuscularly, injected at intervals of 8 to 12 hours.

A 5% "stock" solution (equivalent to 50 mg. of erythromycin base per cubic centimeter) first should be prepared by completely dissolving the equivalent of 0.3 gm. of erythromycin base in 6 cc. (or the equivalent of 1 gm. of base in 20 cc.) of either water for injection or 5% dextrose solution. *Isotonic sodium chloride solution (normal saline) or other inorganic salt solutions should never be used as a solvent for preparing the 5% "stock" solution of erythromycin lactobionate because they cause precipitation of the active ingredient at that concentration.* In the dry form the salt is stable at ordinary temperatures for prolonged periods; the 5% solution is stable for 2 weeks when stored in a refrigerator.

For intravenous injection, the 5% solution should be diluted with not less than four volumes of either 5% dextrose or isotonic sodium chloride solution to make a final concentration of not more than 1% (equivalent to 10 mg. of erythromycin base per cubic centimeter). The calculated dose should be injected slowly over a period of not less than 5 minutes to avoid pain along the course of the vein; alternatively, the calculated intravenous dose may be administered by infusion by diluting this in 200 to 500 cc. of 5% dextrose or isotonic sodium chloride solution.

For intramuscular injection, the 5% "stock" solution is used undiluted. The calculated dose should be injected deeply into a large muscle with extreme care to avoid subcutaneous deposition. The pain following intramuscular injection is caused by transitory local irritation. A single intramuscular dose should not exceed 0.5 gm., as a precaution against the production of tissue damage.

Abbott Laboratories cooperated by f [illegible] fic dat the evaluation of erythrom [illegible] ion

EMPHYSEMA AND ITS RELATIONSHIP TO DUST EXPOSURE

GUEST EDITORIAL

Oscar A. Sander, M.D.

Two recent papers by Heppleston [1] of Cardiff serve to emphasize that there still are many gaps in our basic pathological and physiological concepts of emphysema in general and of the focal emphysema of coal workers' pneumonoconiosis in particular. His meticulous microscopic serial sections of the lungs of coal miners seem to suggest that the focal emphysema that he finds in most of these lungs with simple pneumonoconiosis differs materially from generalized vesicular emphysema and is due primarily to dilation of the respiratory bronchioles around which coal dust deposits are found. His histopathological studies suggest that these coal dust deposits cause atrophy of the smooth muscle of the bronchiolar walls, permitting excessive dilatation of those bronchioles, which in turn increases the dead air space. When this becomes advanced, he believes, interference with exchange of gases and dyspnea on exertion may result, even though the airways are open and no bronchial obstruction exists.

This concept is in sharp contrast with that on which most present-day therapy is based; namely, that disabling emphysema, regardless of its cause, is primarily obstructive due at least in part to bronchospasm and that it can be improved symptomatically by bronchodilator aerosol inhalations and promotion of drainage of bronchial secretions. Motley,[2] Smart,[3] and Fowler [4] have shown good ventilatory improvement with the use of both bronchodilation and intermittent positive pressure breathing. Fowler, however, found that bronchodilation alone gave as good results with his nonminer patients with obstruction as when intermittent positive pressure breathing also was used, suggesting that obstruction due to bronchospasm is the main cause of disturbed function in emphysema that is unrelated to dust exposure. Disabling emphysema associated with dust exposure also had been thought to be due primarily to airway obstruction until the new concept was suggested by the pathological studies of South Wales coal miners' lungs.

As a matter of fact, the functional significance of dilated bronchioles with apparently normal alveoli, such as Heppleston describes, needs further investigation by careful physiological studies. Can focal emphysema alone without airway obstruction cause significant impairment of lung function? Several clews suggest that this may be unlikely. Fletcher [5] and Hugh-Jones [6] have stated repeatedly that coal workers with simple pneumonoconiosis (coal deposits plus focal emphysema) have relatively little disability and that most of the severe disability is found in miners with massive fibrosis. Another clew is furnished in a recent paper by Wells,[7] which indicated that simple coal workers' pneumonoconiosis was not a major contributing factor in the 28 deaths due to failure of the right side of the heart out of 181 autopsies on miners with simple pneumonoconiosis. On the other hand, almost half of 136 with massive fibrosis died of cor pulmonale. In the present state of our knowledge, it seems likely that focal emphysema per se is not a serious cause of impaired lung function. When an apparently real respiratory disability is found in a coal miner showing only simple pneumonoconiosis by chest roentgenogram, it appears that other causes for the dyspnea should be investigated, including heart disease and diffuse obstructive emphysema due to other causes, as well as the aging factor. Fletcher clearly states, "We do occasionally find men with simple pneumonoconiosis who are seriously disabled, but in such cases it is difficult to exclude the possibility that emphysema not of industrial origin is contributing to the disability."

These observations on focal emphysema by the pathologists of the British Pneumonoconiosis Research Unit need confirmation by similar third dimensional microscopic tissue studies, not only for other dust diseases but for emphysema in general. Gough [8] states that he has seen identical changes in the lungs of some hematite miners, foundry workers, and Kolar gold miners where the silica content of the dust is low. He believes that atrophy of bronchiolar smooth muscle may result from excessive deposits of other dusts, including some that we now consider inert, and that this is not a specific property of coal dust. This concept is difficult to comprehend because of the many cases of siderosis of welders, burners, and grinders in which there is neither evidence of emphysema nor disturbed ventilatory function and in which the microscopic sections show no evidence of focal emphysema. We know at least that that form of iron oxide causes no dilation of bronchioles. Why is it then that certain other dusts seem to have that effect?

The whole subject of pulmonary emphysema, whether or not related to the dust diseases, needs further definitive study, and the third dimensional technique seems ideal for the pathological evaluation. Present concepts have been based on a few microscopic sections from many cases, whereas many serial sections from a single case (up to 300 or 400 from a single 2 cc. block) should give far more reliable information. More meticulous lung tissue studies as well as lung function studies, correlated with histopathology, are necessary for a better understanding of the various types of emphysema and their physiological differences. Also lacking are reliable incidence figures on disabling obstructive emphysema in the population at various age levels. Until this information is available, therapy of emphysema will stay more or less empirical and our understanding of emphysema and its relationship to dust exposure more or less clouded.

MORE AND BETTER TEACHERS NEEDED

According to Waterman [1] the number of persons being graduated in this country with a bachelor's or advanced degree in science is decreasing alarmingly. Such graduates are a constant and vital need in carrying on the research, development, and teaching needed to keep this country abreast of the rest of the civilized world. Much of our technological development stems from basic research carried on in a foreign country. Many of our most capable scientists were born in foreign countries and had their early training there. We cannot go on indefinitely relying on foreign sources. There is a special urgency to see that those who do study science are well taught and that there are enough well-qualified teachers to teach them.[2] At present only about 50% of those whose intelligence tests indicate that they would benefit by collegiate training go to college, and less than 2% obtain a Ph.D. degree. If we are to build up one of our most valuable resources, a body of intelligent well-trained scientists, we must increase the broad base of educated population from which most of our leaders in this field must come. To this end more scholarships for promising young scientists and potential teachers are needed. Many industries are now supporting such scholarships.

Recognizing the importance of directing promising young scholars into teaching, Professor Oates of Princeton in 1945 inaugurated a special type of fellowship to which the name Woodrow Wilson program has been given. This program, now operated by the Association of American Universities, selects candidates from a large number of nominees. The student cannot apply for a fellowship but must be nominated by his teacher as showing potential teaching ability. Those who are already definitely headed toward teaching careers are not nominated, but rather those whose futures are undecided. Successful candidates receive one year of graduate work at a school of their own choosing in the United States or Canada. They are placed under no obligation to enter the teaching profession but are merely asked to consider it seriously. About 80% of those selected to date are now in teaching or research positions. One fruitful by-product of the program is that many of the candidates who were not selected have gone into teaching. Thus the psychological effect of confidence in their teaching ability expressed at a critical stage in their development may have been more important than the a [illegible] Another [illegible]d feature of the program is that it increases the awareness of teachers of their role as talent scouts by giving them a part in recruiting persons to swell the ranks.

Finding good potential teachers early and then giving them adequate opportunities and backing is, alone, inadequate. The student's enthusiasm as a potential teacher must be preserved through constant stimulation. One of the best ways of accomplishing this is to allow the teacher to conduct some research. This not only contributes to the sum of human knowledge but also develops the teacher professionally and as a person. To this end the Social Science Research Council has established a faculty research fellowship program; its beneficiaries are freed from half of their teaching duties for three years. Senior professors and academic administrators nominate junior colleagues for these fellowships, which unlike most research grants permit the successful candidate to work in a field of his own choosing. Nothing inspires a developing scientist so much as association with the leaders in his field, as is indicated by the fact that among Nobel prize winners there are many pupils of former winners. We cannot manufacturer teachers and scientists, but we can do much to create an environment of opportunity and encouragement for those who show talent. Much of what has been said of teaching and research in general can find apt application in the field of medical teaching and research.

A LIGHTER TAX BURDEN FOR THE YOUNG

On July 18 the House of Representatives by a vote of 372 to 31 sent to the Senate H. R. 7225 amending the Social Security Act. The Senate did not act on this bill prior to adjournment on August 2. If enacted, the bill would, among other changes, force a number of self-employed groups now excluded—lawyers, dentists, osteopaths, veterinarians, chiropractors, neuropaths, and optometrists, but not physicians—under Old-Age and Survivors Insurance. Probably 30,000 physicians will attain age 72 during the next 15 years. Age 72 is mentioned instead of age 65, the minimum age at which O. A. S. I. pensions are now payable, because the pensions will be payable at age 72 regardless of earnings; and these pensions will entice few physicians when reaching age 65 to promptly quit taking care of the sick. Since these 30,000 physicians would pay on the average less than $1,000 in taxes during the next 15 years and they (and those now over age 72) would become eligible for pension benefits worth about $14,000, it follows that their exclusion from compulsory coverage will save the taxpayers of the future an average of at least $13,000 per physician, or about 400 million dollars. So the decision of the Ways and Means Committee and the House of Representatives to continue to exclude physicians from O. A. S. I. is a boon to the taxpayers of the future. If the Republicans and Democrats during the next 15 years continue to vie with each other in further increasing the windfalls for older workers under O. A. S. I., the boon to the next generation from the continued exclusion of physicians may be much greater than 400 million dollars.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

I would like to take a few moments of your time this month to tell you of some of the things that to my mind are very important. For many years the physician was little interested in politics per se. Occasionally a physician ran for public office, usually with little or no support from his confreres, the majority of his fellow practitioners being satisfied to practice medicine. While they aided the injured and the ill, they were at times even more important as family counselors. In many instances in this respect they were more helpful than the minister, priest, or rabbi, because as doctors their work cut across all sections of the life of a person, a family, and even, at times, the community. For years on end this was the pattern of the physician's life. Then something happened. Suddenly the physician was faced with an extremely serious situation. Where before he had been a completely independent individual, he suddenly found his independence challenged. For the first time in his life he became cognizant of the fact that he could not continue being just a physician but that he had to play a dual role, that of physician and also private citizen. It is concerning the latter aspect that I would like to express my views. In the first place we, as physicians, are citizens of this great country, and along with other citizens we have allowed our affairs to drift into the hands of a minority, evident in both political parties, interested solely in personal power and the necessary votes to continue in their very influential positions. Businessmen and manufacturers also began to realize that certain elements in their own groups were taking personal advantage of political preference and that a certain percentage of businesses were being infiltrated by men of doubtful character. Without publicity even our government likewise became insidiously infiltrated by a group of so-called liberal intellectuals, who, following the Fabian philosophy, began to teach and preach socialism. They would destroy our two-party form of government by making of the free and independent American citizen governed by law a group of subservient citizens governed by men, the citizen a chattel of government. During the past 20 years there has been a real threat that government of the people, by the people, and for the people would disappear from the American scene. By gradual change our lives and our freedoms became more and more uncertain, and, when finally the Fabians in our Congress began actively to press for socialized medicine, the physician suddenly realized that even he who had never been interested actively in governmental gyrations had a job to do if he was to preserve not only his own freedom but that of his neighbors. Even then, however, the physician did not realize fully how important was his franchise. Some of our medical leaders who were constantly in touch with the Washington scene began to write and to talk about the inherent dangers, but it was difficult to rouse the men at the grass roots level to take any action. Most of us were too busy taking care of the sick to be bothered. Some of us who did realize, however, the threat to our personal freedoms and the free enterprise that had made our country really great began to analyze at the local levels our own particular and peculiar problems. We found an amazing situation. First, only about 20% of our physicians and their wives and children of voting age were registered. That meant that those who had been elected to public office paid little, if any, attention to the demands of physicians when it came to legislative matters. This was the natural reaction of our legislators to the indifference of the medical profession. The first thing that several men, to whom we appealed for support, said was that we were not interested enough to vote, so why should we expect favorable cooperation when a much larger segment of the population desired the legislation in question and this group voted. About this time the bills that would socialize medicine were being advocated by some very vocal people, including a professional group called the Physicians Forum and many so-called liberal senators at Washington. One man in particular really challenged the medical profession of his own state on this subject, and, although this man was a Democrat, his Democratic medical constituents decided to do something about it. The physicians as citizens, their wives and friends raised money, saw to it that they were all registered and that their friends were registered, and then in organized groups all over that state pushed doorbells. The result was the overwhelming defeat of a very popular senator. Stimulated by the example of physicians of that state, physicians and their wives and friends in other states did likewise, and many a national and state legislator, elected or defeated, learned to appreciate the effect of a concerted effort of the American physicians.

Today, however, the physician seems to be resting on his oars. The immediate threat of medical socialization at one fell swoop seems to him to be impossible, but he does not realize that socialization of medicine may occur so gradually that we may not notice it. This is the reason for our close scrutiny of all bills that deal with or pertain to health matters at both the state and national levels. It is more imperative than ever for the physicians of this country to take an active interest in all bills concerned in any way with the health problems of the country and, more important, as citizens, to appraise all bills of all kinds so that they may support those that they believe are for the best interest of the public as a whole and oppose those that are not. We can no longer sit by complacently because at the moment everyone is more or less prosperous; we must be continually alert to all of our problems.

All physicians should take a more active interest in all civic affairs. We should be locally active in all movements that will make local living more enjoyable. We must be active in our chambers of commerce, our Red Cross programs, our many other programs for civic betterment sponsored by our local organizations. But most important is that we all be registered t vote and that we do vote. The argument that a single vote is no important is utterly false. Every vote is important.

Every physician in America should see to it that he is registered in the party of his choice, that his wife and children of voting age are registered, and that the people to whom he ministers are registered and that they all vote. The county society should organize its members for the same purpose. They should see that each member is registered in the party of his choice and should attempt to get him to vote. Even the woman's auxiliary should be encouraged to have its membership registered, and their voting should be urged on all issues. County societies should know the legislative issues and the voting record of every man of both parties on all of them—not only those concerning health but all issues. This is a citizen's obligation. Just as I have said so often: The A. M. A. is you as in a greater and broader sense the government is you. We get the kind of government and laws that we deserve, and, unless we are all out working 24 hours a day not only as physicians but as American citizens, we do not deserve very much.

Elmer Hess, M.D., Erie, Pa.

ORGANIZATION SECTION

COUNCIL ON MEDICAL SERVICE

Following are abstracts of actions by the Council on Medical Service as a result of meetings during the Annual Meeting in Atlantic City, N. J., June, 1955.

ELECTION OF CHAIRMAN

J. D. McCarthy, M.D., of Omaha was unanimously elected to serve as Chairman of the Council.

PROFESSIONAL LIABILITY INSURANCE

The Council voted to send to the Board of Trustees a report on professional liability insurance.

NEWSLETTER

The Council requested the staff to prepare a prospectus for a regular medical service newsletter for review by the Council at its next session. In discussing the subject of health councils, it was also suggested that the staff prepare a prospectus of a suitable type of newsletter for health councils.

COMMITTEE APPOINTMENT

David Henry Poer, M.D., Atlanta, Ga., was appointed to serve as a member of the Committee on Medical and Related Facilities.

GENERAL PRACTICE COMMITTEE

The Council submitted to the Board of Trustees the name of Arthur C. Scott Jr., M.D., as its representative to serve on a special committee on general practice.

SURVEY ON AVAILABILITY OF CIVILIAN PHYSICIANS

In response to a request from the Board of Trustees the Council submitted recommendations regarding a survey to determine the availability of civilian physicians to provide certain medical services currently provided in military facilities. After approval by the Board, it was voted to make pilot surveys in cooperation with the Council on National Defense and with the assistance of the local medical societies involved.

PROGRESS REPORT ON MEDICAL SCHOOL STUDY

The Council voted to submit to the House of Delegates a progress report on the medical school study having to do with programs for supplementing through private practice the incomes of full-time teachers in medical schools. In connection with this study the Council approved the mailing of a questionnaire to state and local medical societies to learn something of the attitude of the local profession toward the operating policies of medical schools.

HOUSE OF DELEGATES' RESOLUTIONS

Reports and recommendations regarding the following resolutions were approved for transmittal to the Board of Trustees: (1) Resolution (No. 11—1954 Clinical Session) on Better Liaison with Health and Accident Insurance Carriers; (2) Resolution (No. 1—1954 Clinical Session) on Agreements between Prepayment Plans and Organized Medicine; and (3) Resolution (No. 12—1954 Clinical Session) on Relationships Between Component County Societies and Lay Sponsored Health and Welfare Plans.

PUBLICATION ON COMPULSORY SICKNESS INSURANCE

The Council approved the preparation of a booklet on compulsory sickness insurance in cooperation with the Department of Public Relations. It was recommended that the booklet be directed to physicians and the public.

MANAGEMENT AND UNION HEALTH CENTERS

The Council on Medical Service and the executive committee of the Council on Industrial Health voted to submit to the House of Delegates the "Guiding Principles for Evaluating Management and Union Health Centers," originally prepared by the Committee on Medical Care for Industrial Workers. It was further voted that the members of the House be requested to review the principles prior to the 1955 Clinical Session.

CONFERENCE IN BITUMINOUS COAL MINING AREA

The Council authorized the Committee on Medical Care for Industrial Workers to hold its fourth conference on medical care in the bituminous coal mine area.

PHYSICIANS ATTITUDES QUESTIONNAIRE

The Council authorized the Committee on Prepayment Medical and Hospital Service to meet with a committee of the Blue Shield Commission for a discussion of the responses to the Physicians Attitudes Questionnaire. The Committee was also authorized to publish data on this survey.

SIMPLIFIED CLAIM FORMS

The Council voted approval of the following simplified claim forms submitted by the Health Insurance Council with the understanding that on first reprint the forms be modified as suggested by the Committee on Prepayment Medical and Hospital Service: IPHS-1, ID-1, IDS-1, GD-1, and GDS-1. These forms are for individual hospital or surgical accident or sickness insurance and for various types of group insurance.

PHYSICIANS PLACEMENT SERVICE

The Council staff was authorized to make a concerted effort to learn of available openings for specialists in view of the volume of requests being received from such physicians.

LISTING OF COUNCIL PUBLICATIONS

A listing of various Council publications in indexes and bulletins used as reference sources by libraries and schools was authorized.

HILL-BURTON AMENDMENTS

The Council instructed the Committee on Medical and Related Facilities to collect facts and data regarding the Hill-Burton Act with particular emphasis on the section of the new regulations dealing with diagnostic and treatment centers.

VOLUNTARY HEALTH INSURANCE

At the request of the Board of Trustees the Council considered a proposed resolution on voluntary health insurance and recommended that it be referred to the Commission on Medical Care Plans.

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Federal Aid for Public Health Education

Senator Humphrey (D., Minn.), in S. 1859, proposes to provide a five year emergency grant and scholarship program for postgraduate study in schools of public health. Over a five year period he would authorize 5 million dollars for outright subsidies, 5 million dollars for construction grants on a 50-50 matching basis, and a total of 250 million dollars for scholarships. He would provide grants on a basis of 15% of the basic operating costs of graduate instruction plus "an additional sum of $500 for each full-time student regularly enrolled for the fiscal year for graduate work in public health in excess of thirty such students; and an additional sum of $500 for each full-time student regularly enrolled for the fiscal year for graduate work in public health in excess of its average past enrollment of such students." The maximum per school would be 50% of the basic operating cost of the school. This measure would be administered by the surgeon general of the Public Health Service. The bill was referred to the Committee on Labor and Public Welfare.

Distribution and Use of Serum

Congressman Priest (D., Tenn.), in H. R. 6207, would authorize the Secretary of Health, Education, and Welfare to supervise and control the distribution and use of any virus,

---

From the Washington Office of the American Medical Association.

serum, toxin, antitoxin, and analogous products when the Secretary deems such action necessary to protect and preserve the health of the American people. The present authority prohibits the sale or distribution of such products unless the manufacturer has been licensed and the packages are labeled properly. This bill was referred to the Committee on Interstate and Foreign Commerce.

Cash Disability Insurance Under Social Security

Senator Potter (R., Mich.) proposes, in S. 2094, "to amend Title II of the Social Security Act so as to reduce from 65 to 60 years the age at which wives and widows may qualify for old age and survivors insurance benefits and to provide for the payment of disability insurance benefits," after a six months' waiting period with payments reduced by workmen's compensation benefits, if any. The amount of benefits would be figured on the same formula as old age benefits but would be subject to reduction if the disabled person refuses rehabilitation evaluation and training or fails to submit himself for examination. This bill was referred to the Finance Committee.

Chiropractors in the VA

Congresswoman Rogers (R., Mass.) by request has introduced, in H. R. 6311, a measure that would "authorize the appointment of doctors of chiropractic in the Department of Medicine and Surgery of the Veterans' Administration." Such doctors of chiropractic must "hold a degree of doctor of chiropractic from a school or college approved by the Administrator, be licensed to practice chiropractic in one of the states or territories of the United States or in the District of Columbia, and have practiced chiropractic for a period of at least two years." This bill was referred to the Committee on Veterans' Affairs.

Agency for the Handicapped

Senator Neely (D., W. Va.), in S. 1951; Congressman O'Hara (D., Ill.), in H. R. 6065; Congressman Doyle (D., Calif.), in H. R. 6718; and Congresswoman Kee (D., W. Va.), in H. R. 6960, have introduced identical bills in a series of identical bills to establish an agency for the handicapped to be placed in the Department of Labor. The present functions of the Office of Vocational Rehabilitation would be transferred from the Department of Health, Education, and Welfare to the new agency. Provision is made for: (*a*) payment, through the states, of a $60 per month pension to all handicapped persons whose rehabilitation is unfeasible, (*b*) a revolving loan fund to assist in the financing of state programs, and (*c*) establishment of a new division for the handicapped within the Civil Service Commission and the United States Employment Service. The previous bills are as follows: H. R. 5465 by Bennett (D., Fla.), H. R. 5471 by Dingell (D., Mich.), H. R. 5487 by Withrow (R., Wis.), H. R. 5510 by Knutson (D., Minn.), H. R. 5513 by McCormack (D., Mass.), H. R. 5523 by Tollefson (R., Wash.), H. R. 5571 by Rhodes (D., Pa.), H. R. 5603 by Kelley (D., Pa.), H. R. 5705 by Buchanan (D., Pa.), H. R. 5737 by Chudoff (D., Pa.), H. R. 5859 by Saylor (R., Pa.), H. R. 5874 by Bailey (D., W. Va.), H. R. 5939 by Buckley (D., N. Y.), H. R. 5971 by Rabaut (D., Mich.), and H. R. 6064 by Madden (D., Ind.). The Senate bill was referred to the Committee on Labor and Public Welfare. The House bills were referred to the Committee on Education and Labor.

Male Nurses as Reserve Officers

Senator Saltonstall, in S. 2050, and Congresswoman Bolton, in H. R. 2559, have introduced the Defense Department measure to authorize the commissioning of men as reserve officers in the Military Nurse Corps under the same provisions of law as are applicable to women. These bills were referred to the respective armed services committees.

Federal Aid to Medical Education

Congressman Elliott (D., Ala.) has introduced an identical measure with S. 1323 and H. R. 4743, previously reported. This bill would authorize 250 million dollars over a period of five years in grants for construction of medical education and research facilities for our accredited public and private medical schools. The bill was referred to the Interstate and Foreign Commerce Committee.

Loans for College Students

Congressman Poage (D., Texas), in H. R. 6304, would authorize the Secretary of the Department of Health, Education, and Welfare to lend up to $1,500 per year to eligible college and university students "to assist them in pursuing courses of education (including postgraduate courses) at accredited colleges and universities in the United States." The course of study could include medicine. The rate of interest would be 3% from the date the borrower leaves school. The loan would be repayable in five annual installments, beginning on the fifth anniversary of the date of the loan after the borrower has left school. Overdue and extended balances would carry an 8% interest rate. This bill was referred to the Committee on Education and Labor.

Prohibition of Severance of Ten Year Service Connection

Congresswoman Rogers (R., Mass.), in H. R. 6312, proposes "to prohibit the severance of a service-connected disability 'connection' which has been in effect for ten or more years . . . unless on a showing that the original rating was based on fraud or gross misrepresentation." This bill was referred to the Committee on Veterans' Affairs.

Cancer Research

Congressman Chiperfield (R., Ill.), in H. R. 6473, would "authorize and request the President to undertake to mobilize at some convenient place in the United States an adequate number of the world's outstanding experts, and coordinate and utilize their services in a supreme endeavor to discover means of curing and preventing cancer." This bill was referred to the Committee on Foreign Affairs.

Air Pollution Control

Congressman Hiestand (R., Calif.), in H. R. 6597, and Congressman Roosevelt (D., Calif.), in H. R. 6699, have introduced identical measures with S. 928, which would provide research and technical assistance related to air pollution control. S. 928 was reported in THE JOURNAL, April 16, 1955, page 1413, and was passed by both Houses and signed by the President and is Public Law 159. The Committee on Interstate and Foreign Commerce handled this measure in the House. Senator Sparkman (D., Ala.), in S. 2126, in the extension of the housing and slum clearance provisions of the National Housing Act proposes to authorize 50 million dollars for air pollution control and prevention loans. The Secretary of Health, Education, and Welfare would be given funds for technical research studies concerned with air pollution and excessive smoke. This measure is similar to S. 1565, previously reported. The measure was referred to the Committee on Banking and Currency.

Active Tuberculosis Deemed Permanently and Totally Disabling

Congressman Dorn (D., S. C.), in H. R. 6685, proposes to amend the Veterans Regulations concerning disabilities or death not as a result of service to provide that "active tuberculosis shall be deemed permanently and totally disabling." This bill was referred to the Veterans Affairs Committee.

Presumption of Service Connection for Leprosy

Congresswoman Rogers (R., Mass.), in H. R. 6698, proposes to amend the Veterans Regulations to increase from one to three years the period after discharge during which leprosy if diagnosed would be considered service connected. This bill was referred to the Committee on Veterans Affairs.

Presumption of Service Connection for Tuberculosis

Congressman Moulder (D., Mo.) proposes, in H. R. 7579, to amend the Veterans Regulations to establish that "where any individual who has been rated as totally disabled for ten consecutive years or more from active tuberculosis of any type dies, the death of such individual shall be conclusively presumed to be the result of disease incurred or aggravated in line of duty in the active military or naval service." This measure was referred to the Committee on Veterans Affairs.

Family Allowances for Health and Well-Being of Children

Senators Neuberger (D., Ore.), Morse (D., Ore.), Douglas (D., Ill.), Humphrey (D., Minn.), Lehman (D., N. Y.), Kennedy

(D., Mass.), McNamara (D., Mich.) propose, in S. Res. 109, to create a special congressional committee to study the family allowance program in Canada to determine the advisability of instituting legislation for a similar program in the United States. This bill was referred to the Committee on Labor and Public Welfare.

Compulsory Social Security for Self-Employed

Congressman Johnson (D., Wis.) proposes, in H. R. 6811, "to extend coverage under the Federal old-age and survivors insurance system to self-employed physicians, lawyers, dentists, and veterinarians." This measure was referred to the Committee on Ways and Means.

Silicosis Research

Senator Welker (R., Idaho) proposes, in S. 2299, to establish a national industrial health institute in the National Institutes of Health to conduct broad research training in prevention, control, and cure of silicosis and other industrial diseases. The surgeon general of the Public Health Service would be authorized to make grants-in-aid to universities, hospitals, and individuals for research projects and traineeships. A national advisory industrial health council would be established. This measure was referred to the Committee on Labor and Public Welfare.

Chronic Alcoholism

Congressman Gubser (R., Calif.), in H. R. 6837, would authorize the Secretary of Health, Education, and Welfare to institute a program of research and treatment with respect to chronic alcoholics. The program would "include the establishment of an institute (or the expansion of an existing institute) . . . to conduct and support scientific research and professional training relating to the cause, prevention, and methods of diagnosis and treatment of chronic alcoholism; the establishment or expansion of a national advisory council . . . to advise, consult with, and make recommendations to the Surgeon General on matters relating to chronic alcoholism; and the establishment of traineeships and fellowships. . . . Such program shall also provide for assistance to and cooperation with states conducting research and treatment programs with respect to chronic alcoholism." This measure was referred to the Committee on Interstate and Foreign Commerce.

National Library of Medicine

Congressman Fisher (D., Texas), in H. R. 6915; Senator Smith (R., N. J.), in S. 2408; Senator McCarthy (R., Wis.), in S. 2482; Congresswoman Church (R., Ill.), in H. R. 7344; and Congressman Frelinghuysen (R., N. J.), in H. R. 7528, have introduced identical measures to establish a national library of medicine in keeping with the recommendations of the Hoover commission. The site for the national library of medicine would be in the District of Columbia, and to this library would be transferred "all property, records, personnel, and unexpended balances of appropriation, allocations, and other funds available or to be made available, of the Armed Forces Medical Library." The library would be a division of the Smithsonian Institution but would have its own board of trustees, which would be selected by the board of regents of the Smithsonian Institution. The Senate bills were referred to the Committee on Labor and Public Welfare. The House bills were referred to the Committee on House Administration.

Military Credit for Civilian Intern Training

Congressman Lane (D., Mass.) has proposed, in H. R. 4810, to give credit to active and retired officers of the medical departments of the Army and Air Forces for all service personnel as civilian interns in Army hospitals on the civilian employee basis in calculating promotion longevity pay. This measure was referred to the Committee on Armed Services.

MR. HOLLOWAY RETIRES

Mr. J. W. Holloway Jr., who served nearly 30 years with the American Medical Association, many of them as Director of the old Bureau of Legal Medicine, has retired and soon will move to Smithfield, Va., where he was born. He will, for the time being at least, retain his membership on the A. M. A. Committee on Medicolegal Problems.

TEXAS TO HOLD FIRST PUBLIC RELATIONS CONFERENCE

The Texas Medical Association is holding its first annual public relations conference early in September. This conference, tailored to fit the needs of public relations workers at the county level, is the first attempt by the state association to bring local chairmen together for a program especially planned for them. Executive Secretary C. Lincoln Williston has worked up a program that includes every phase of medical public relations, including external projects such as health forums, health fairs, and exhibits. Members of the Texas committee on public relations, headed by Dr. William M. Crawford, Fort Worth, will be hosts at the conference. A. M. A. Public Relations Director Leo Brown is scheduled to speak on "Public Relations and Its Application to Medicine." He also will take part in a panel discussion on "PR Programming for County Societies." John L. Bach, director of A. M. A. press relations, will speak on "Doctor-Press Relations at the County Society Level" and will take part in a panel discussion on the subject, which will include a review of work by grievance committees.

MEETING ON HEALTH OF COAL MINERS

To explore ways of improving liaison between medical societies and area medical administrators of the United Mine Workers Welfare and Retirement Fund, the American Medical Association will sponsor the fourth Conference on Medical Care in the Bituminous Coal Mine Area this fall. The conference will be held Oct. 2 in Charleston, W. Va., under the auspices of the Council on Industrial Health and the Council on Medical Service. Representatives of the liaison committee and officers of the UMW Welfare and Retirement Fund of the five states in the country's principal coal-mining areas have been invited to attend. A number of other states interested in these problems also will send representatives.

LEAFLET FOR YOUR PATIENTS

An attractive new leaflet earmarked for patients only will be distributed in September to members of the A. M. A. Entitled "To All My Patients," this 12-page pamphlet (for physicians to distribute to their patients) explains the roles of various persons on the medical team in providing good medical care. In addition, the booklet briefly discusses medical and hospital fees and health insurance. Designed primarily to promote better doctor-patient relationships, the booklet also provides space for the doctor's name, address, and office hours to be inserted at the end. Quantities will be available on request from the A. M. A. Public Relations Department.

STUDY OF GRIEVANCE COMMITTEE OPERATIONS

Standards for medical society grievance or mediation committees are being developed by a special committee appointed by the A. M. A.'s Board of Trustees. A group of consultants—state executive secretaries Rowland B. Kennedy, Mississippi; Harvey T. Sethman, Colorado; and John E. Farrell, Rhode Island—and several A. M. A. staff members are visiting some 25 state medical associations to collect information on grievance committee organization and operation. Those states not visited will receive a survey form that should be submitted to the committee if the society wishes its grievance committee program to be included in this study. In addition, a special survey form will be sent to about 70 county medical societies. Personal visits also will be made to selected societies having a variety of types of grievance committees.

COMMITTEE ON RESEARCH

Dr. Norman De Nosaquo, who served 16 years as a member of the division of medicine of the Food and Drug Administration in Washington, has taken over as Secretary of the A. M. A. Committee on Research, a job formerly held by Dr. Paul L. Wermer, who resigned to join an eastern pharmaceutical company. Dr. De Nosaquo was graduated from the University of Wisconsin Medical School in 1927.

MEDICAL NEWS

CALIFORNIA

Postgraduate Lectures.—A Lecture Series on Obstetrics, Gynecology, and Dermatology will be sponsored by the Riverside-San Bernardino chapter of the American Academy of General Practice cooperating with the school of medicine and medical extension on the Los Angeles campus of the University of California, with monthly meetings, Sept. 15-May 17. The first lecture in the series will be at 7 p. m., Sept. 15, when "Eclamptogenic Toxemia" will be presented by Dr. Nicholas S. Assali, Los Angeles, at the Mission Inn, Riverside. Lectures are scheduled for the third Thursday monthly at various locations. The fee for the series, $37.50, does not include the dinner preceding the lectures. Requests for information should be made to Dr. Thomas H. Sternberg, University of California Medical Center, Los Angeles 24 (Granite 89711, station 202), or to Dr. Walter A. Sullivan, 108 E. H St., Ontario (telephone 622-106).

FLORIDA

Appoint Department Head.—Frank W. Putnam, Ph.D., formerly a staff member of the Argonne Cancer Research Hospital in Chicago, has been named head of the department of physiological chemistry of the University of Florida College of Medicine, Gainesville. Dr. Putnam, who will assume his new position Sept. 1, has been affiliated with Duke University School of Medicine, Durham, N. C., Stritch School of Medicine of Loyola University, Chicago, the University of Chicago, and the University of Cambridge, England. He is editor of the *Archives of Biochemistry and Biophysics* and 1955 chairman of the AAAS Gordon Conference on Proteins and Nucleic Acids.

ILLINOIS

Discussions on the Cancer Quack.—The Illinois division of the American Cancer Society has scheduled six district meetings for the fall:

First District, Sept. 15, Messiah Lutheran Church, Sterling.
Second District, Oct. 20, Hotel Custer, Galesburg.
Third District, Sept. 8, First Methodist Church, Pekin.
Fourth District, Sept. 29, Masonic Temple, Jacksonville.
Fifth District, Oct. 6, Moose Club, Champaign.
Sixth District, Oct. 13, Herrin Elks Club, Herrin.

Mr. Oliver Field, Chicago, Director of the Bureau of Investigation, American Medical Association, the featured speaker at all the district meetings, will discuss the cancer quack.

Chicago

Volunteer Medical Company.—A meeting of the Volunteer Medical Company 9-20, U. S. Naval Reserve, will be held at the U. S. Veterans Research Hospital, Room A-302, 333 E. Huron St. (MOhawk 4-6600), at 8:15 p. m., Sept. 6. "Surgery of the Heart for Acquired Heart Disease" will be presented by Dr. Herbert D. Trace.

Professorial Promotions.—The following members of the Northwestern University Medical School faculty have been promoted to the rank of full professor effective Sept. 1: Dr. William J. Baker, Chicago, professor of urology; Dr. John M. Dorsey, Chicago, professor of surgery; Dr. Benjamin M. Kagan, Chicago, professor of pediatrics; George K. Yacorzynski, Ph.D., Evanston, professor of neurology and psychiatry; and Dr. Samuel J. Zakon, Chicago, professor of dermatology.

Personal.—Dr. Josiah J. Moore, a native of Montana, for many years Treasurer of the American Medical Association, has been elected to honorary membership in the Montana Medical Association.——Dr. Aldo A. Luisada has been named editor-in-chief of the forthcoming "Encyclopedia of Cardiology," a two volume encyclopedia, published by the American College of Cardiology, which will cover the clinical aspects of cardiology and data and problems of allied sciences.——Dr. Richard A. Perritt addressed the International College of Surgeons in Geneva, Switzerland, May 23, on "The Ridley Intra-Ocular Acrylic Lens Operation—Comments and Modifications."——Dr. Edwin L. Crosby, director of the American Hospital Association, Chicago, has been elected to the board of trustees of his alma mater, the Albany (N. Y.) Medical College of Union University. Dr. Crosby, first director of the Joint Commission on the Accreditation of Hospitals and former director of the Johns Hopkins Hospital in Baltimore, has been research director for the Hoover Commission Medical Task Force.——Dr. William F. T. Kellow, instructor in medicine at the University of Illinois College of Medicine, will assume his duties as assistant dean and assistant professor of medicine Sept. 1. He has been assistant chief of medicine at the west side Veterans Administration Hospital since September, 1953.——Presbyterian Hospital has appointed Dr. Theodore B. Schwartz as chief of the recently established endocrinology and metabolic diseases division of its department of medicine. The division will conduct investigations in endocrinologic and metabolic disorders under a grant from the John A. Hartford Foundation. Dr. Schwartz has been assistant chief of medicine since 1953 at the Veterans Administration Hospital, Durham, N. C.

IOWA

Institute on Agricultural Medicine.—A grant of $109,000 for support of the nation's first Institute of Agricultural Medicine has been awarded to the State University of Iowa, Iowa City, by the W. K. Kellogg Foundation. The institute will be set up to conduct medical and social research on the diseases to which farm people are especially susceptible and to develop new measures to safeguard the farmer's health. The new unit will be under the jurisdiction of Dr. Franklin H. Top, head of the department of hygiene and preventive medicine. In addition to studies on the 88 known diseases transmitted from animal to man, the institute will bring studies to bear on skin diseases due to contact with chemicals and plants; impurities in water, milk, milk products, and other foods; the effects of chemical fertilizers and insect sprays on the agricultural worker and the consumer; mental depression among rural workers; and farm accidents.

LOUISIANA

Graduate Medical Assembly.—The ninth annual meeting of the Southwest Louisiana Graduate Medical Assembly will be presented by the Calcasieu Parish Medical Society at the Majestic Hotel, Lake Charles, Sept. 16-17. Guest speakers include:

William F. Guerriero, Dallas, Texas, The Indefinite Pelvic Mass—Problem and Solution. Differential Diagnosis of Vaginal Bleeding.
Mervin H. Grossman, Dallas, Texas, Use and Abuse of Blood Transfusions. Now the Rh Baby Can Be Saved.
Bedford F. Boylston, Houston, Texas, Whiplash Injuries of the Cervical Spine. Treatment of Common Injuries of Upper Extremities.
Patrick H. Hanley, New Orleans, Presacral Inclusion Cysts. Common Lesions Seen in Proctoscopic Examination.
Charles L. Martin, Dallas, Texas, Treatment of Cancer of the Skin.
Samuel B. Nadler, New Orleans, Specific Correction of Surgical-Medical Electrolyte Imbalance. Present Concepts in the Laboratory Diagnosis of Liver Disease.
Walton R. Akenhead, New Orleans, subjects to be announced.

The program will include lectures, "curbstone" consultations, clinicopathological conferences, round-table luncheons, medical motion pictures, scientific exhibits, and technical exhibits. Registration fee, $10. For information write Mrs. Pat Seaman, Assistant Secretary, P. O. Box 568, Lake Charles, or phone HEmlock 6-9551, Ext. 201.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

MASSACHUSETTS

Appoint Associate Dean.—Dr. Lamar Soutter, Dedham, associate professor of surgery at the Boston University School of Medicine since 1952, has been appointed associate dean. During World War II Dr. Soutter served in the Army Medical Corps with the First and Third Armies. From 1946 to 1952, he was an instructor in surgery at his alma mater, the Harvard Medical School, Boston. He was chairman of the Massachusetts Medical Society's committee for the supervision of the Red Cross Blood Program from 1949 to 1952 and was president of the New England Association of Blood Bank Directors, 1950 to 1952.

MISSOURI

University News.—The Saint Louis University School of Medicine announces the appointment of the following St. Louis physicians: Andrew L. Hahn, instructor in internal medicine; Frank J. Valach, assistant in gynecology and obstetrics; Robert Rochman, assistant in neurology and psychiatry; James W. Nofles, assistant in ophthalmology; and, as assistants in internal medicine, St. Louis physicians Murray Chinsky, Henry T. Cooper, Sidney Goldenberg, and Dr. Albert M. Huggins of Overland.

Dr. Doisy Honored.—St. Louis University has honored its Nobel-prize-winning biochemist, Edward A. Doisy, Ph.D., by naming the department of biochemistry for him. The announcement was made at a dinner celebrating the 25th anniversary of the assignment of patent and licensor rights to the university by Dr. Doisy for the manufacture and sale of Theelin, the ovarian hormone isolated by him and his associates in 1929. A plaque placed at the entrance to the department reads, "In recognition of discoveries which have revealed the truth of nature's secrets and advanced man's well-being, St. Louis University, paying tribute to the genius and generosity of a servant of truth and a guardian of welfare, hereby names and dedicates this department the Edward A. Doisy Department of Biochemistry. On the twenty-fifth anniversary of the assignment of patent and licensor rights to the University by Dr. Doisy, February, 1955."

NEBRASKA

Rehabilitation Institute.—Creighton University School of Medicine, Omaha, the State League for Nursing, and the Nebraska Arthritis and Rheumatism Foundation will sponsor an Institute on Rehabilitation of Neuromuscular and Rheumatic Diseases at Creighton Memorial St. Joseph's Hospital Sept. 8-10. Guest speakers will be Dr. Joseph G. Benton, New York; Dr. William A. Spencer, Houston, Texas; and Dr. William D. Robinson, Ann Arbor, Mich. For information write Dr. Harold N. Neu, Medical Director, Department of Rehabilitation, Creighton Memorial St. Joseph's Hospital, Omaha.

NEW YORK

Bequests for Student Medical Care.—A bequest of more than $400,000 from the late Dr. Clarence P. Oberndorf, who left the residue of his estate to his alma mater, Cornell University, "for the psychiatric treatment of students in the university," will in part provide funds to operate the mental health division of the Cornell student medical service. The bequest is the second major gift to the Cornell health service this year. In February a grant of $450,000 was made by the Gannett Foundation for a campus medical clinic in honor of Frank E. Gannett of Rochester, president of the Gannett Newspapers and a Cornell graduate and trustee.

Course in Tuberculosis of Childhood.—The department of pediatrics of New York University College of Medicine will present a course in tuberculosis for pediatricians and general practitioners at the chest clinic of the Children's Medical Service of Bellevue Hospital Sept. 26-30. This course, designed for pediatricians or general practitioners interested in tuberculosis in infants and children, will be comprised of lectures, clinical demonstrations, and discussions of the diagnosis, prognosis, and treatment of tuberculosis and other pulmonary disorders. The tuition is $60. Those interested should apply to Dr. Edith M. Lincoln, Bellevue Hospital, New York 16.

New York City

Occupational Medicine Course.—Lectures on occupational medicine will be given 9-10 a. m. on Saturdays beginning Sept. 17, in Amphitheater A, Columbia University College of Physicians and Surgeons, 630 W. 168th St., by members of the staff of the division of occupational medicine of the school of public health. Members of the medical and allied professions are invited. There will be no formal registration and no tuition fee. The schedule is as follows:

Sept. 17, History, Scope, Objectives, and Practice of Occupational Medicine.
Sept. 24, Industrial Toxicology—General Principles.
Oct. 1, Toxic Metals 1.
Oct. 8, Toxic Metals 2.
Oct. 15, Toxic Solvents 1.
Oct. 22, Toxic Solvents 2.
Oct. 29, Toxic Dusts.
Nov. 5, Toxic Gases.
Nov. 12, Ventilation, Lighting, Noise.
Nov. 19, Elementary Nuclear Physics; Radiation Hazards.
Nov. 26, written examination (optional for visitors).

Personal.—Dr. George T. Pack will deliver the salutation address at the opening of the Woman's Medical College in Philadelphia Sept. 9.——Dr. Maxwell H. Poppel, chairman, department of radiology, New York University College of Medicine, has been appointed consultant in radiology to the U. S. Naval Hospital at Bethesda, Md.——Dr. R. Frederick Shepard was recently appointed medical director of the Rehabilitation Center of Hawaii in Honolulu.——Dr. Edward W. Lowman, clinical director, Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, recently left to be guest of the dean of University of Chile medical school, Santiago. He was invited to act as consultant to the medical school in planning the establishment of a department of physical medicine and rehabilitation.——Dr. Gregory Zilboorg, clinical professor of psychiatry, State University of New York College of Medicine at New York City in Brooklyn, has been elected vice-president of the International Congress of Criminology to be held in London, England, Sept. 11-18.——Dr. T. Campbell Thompson has been appointed surgeon-in-chief of the Hospital for Special Surgery and professor of clinical surgery (orthopedics) of Cornell University Medical College, succeeding Dr. Philip D. Wilson, who retired July 1 from the position of surgeon-in-chief to become the hospital's director of research and education.

OHIO

Personal.—Dr. Robert H. Bishop Jr., Cleveland, has been awarded the American Social Hygiene Association's William Freeman Snow medal. Since 1947, Dr. Bishop has been director of the Joint Committee for the Advancement of Medical Education and Research of the Western Reserve University School of Medicine and affiliated hospitals.

Anesthesiologists Meet in Toledo.—The Ohio Society of Anesthesiologists will present their annual scientific program at the Commodore Perry Hotel, Toledo, Sept. 10. Presentations by out-of-state speakers will include "Blood Loss During Surgery in Infants and Children" by Dr. Robert M. Smith, Boston, and "Present State of Hypothermia" by Dr. Alexander B. Stearns, Detroit. Dr. Smith will participate in the concluding panel discussion, "Problems in Pediatric Anesthesia," for which Dr. Nicholas G. DePiero, Cleveland, will serve as moderator.

OKLAHOMA

Society News.—Dr. Dixon N. Burns has been named president of the newly organized Tulsa Obstetrical and Gynecological Society; Dr. Walter B. Sanger, president-elect; Dr. W. Carl Lindstrom, vice-president; Dr. Jed E. Goldberg, secretary-treasurer; and Dr. William F. Thomas Jr., member of the executive committee. Beginning in September the society will hold monthly meetings featuring distinguished guest speakers.

Full-Time Pediatrics Department Head.—Dr. Henry B. Strenge, who has been affiliated with the University of Oklahoma since 1947, became the first full-time head of its department of pediatrics on July 1. In line with the school's policy of having full-time men to head the major clinical departments, he succeeds Dr. Clark H. Hall, a practicing pediatrician, who will continue as professor of pediatrics. A graduate of Yale University School of Medicine, Dr. Strenge interned at New Haven (Conn.) Hospital and completed his residency work in pediatrics at Strong Memorial-Rochester Municipal Hospitals, Rochester, N. Y.

SOUTH CAROLINA

Surgical-Medical Meeting.—The combined meeting of the South Carolina chapter of the American College of Surgeons and the annual medical meeting of the staff of the Self Memorial Hospital, Greenwood, will be held Aug. 27 in Greenwood. The following program has been planned:

Management of the Dehydrated Child, Nelson K. Ordway, New Orleans.
Immediate Management of the Accident Victim, Moore Moore Jr., Memphis, Tenn.
Diagnosis and Treatment of Hematological Malignancies, R. Wayne Rundles, Durham, N. C.
Surgical Treatment of Carcinoma of the Cervix, William W. Daniel, New York.
Spontaneous Rupture of the Esophagus, George H. Bunch, Columbia.
Palliative Procedures in Advanced Breast Cancer, Joseph H. Farrow, New York.
Head Injuries, Edgar F. Fincher, Emory University, Ga.
The Ulcer Problem, Philip Thorek, Chicago.

TEXAS

Annual Clinical Conference.—The ninth annual North Texas-Southern Oklahoma Fall Clinical Conference will convene at the Wichita Falls Country Club Sept. 17. Dr. Roger W. Manar, Wichita Falls, president, Wichita County Medical Society, will deliver the address of welcome at 9:15 a. m., after which "Diagnosis and Treatment of Eruptions of Hands and Feet" will be presented by Dr. Clarence S. Livingood, Detroit; "Prolonged Labor" by Dr. John H. Randall, Iowa City; and "Diagnosis and Treatment of Varicose Veins" by Dr. I. Mims Gage, New Orleans. The round-table luncheon will be preceded by Dr. Livingood's paper, "Use of Cortisone, Hydrocortisone and ACTH in Skin Eruptions." The afternoon session will open at 2:30 p. m. with "Headache" by Dr. W. Grady Reddick, Dallas, after which Dr. Randall will discuss "Office Gynecology" and Dr. Gage, "Treatment of Benign and Malignant Pigmented Moles." A cocktail hour, 6:30 p. m., will precede the informal dinner dance. Registration fee, $8, covers scientific sessions, a round-table luncheon, cocktail party, and dinner dance. There will be an additional charge of $4 for bringing a guest to the dance.

WEST VIRGINIA

State Health Conference.—The 31st annual meeting of the State Health Conference will be held at the Daniel Boone Hotel, Charleston, Sept. 7-9. The main topic for discussion will be "Current Problems in Maternal and Child Health" and the main conference theme, "What Is Happening in Public Health in West Virginia?" The fourth annual Health Education Workshop, meeting conjointly with the State Health Conference, will have as its theme "Current Developments in Health Education in West Virginia." Subjects to be discussed include "Current Status of Public Health in West Virginia" and "Local Responsibility for Providing Local Health Services." The conference program will include presentation of "Current Status of Public Health in West Virginia," Dr. Newman H. Dyer, director, state department of health, Charleston; "Local Responsibility for Providing Local Health Services," Dr. Eugene A. Gillis, regional medical director, region 3, U. S. Public Health Service, Washington, D. C.; "Public Health Career Evaluation, Based upon Study in Charleston and Kanawha County," A. L. Lively, sanitarian, Kanawha-Charleston Health Department, Charleston; and a panel discussion, "Local Responsibility for Providing Local Health Services," with Fred J. Holter, Ph.D., Morgantown, as moderator. Dr. Samuel M. Wishik, Pittsburgh, and Ruth G. Taylor, Children's Bureau, Washington, D. C., will present papers on current trends in maternal and child health. Dr. Dyer will be the master of ceremonies at the annual dinner Thursday.

GENERAL

Index Number of The Journal.—The index for the current volume [158] of THE JOURNAL will be printed in the Sept. 10 issue.

Joint Meeting of Physiologists.—The Society of General Physiologists will hold its annual meeting Sept. 9 to 10 jointly with the American Physiological Society, which has scheduled its annual meeting for Sept. 6 to 9 at Tufts University, Medford, Mass. The Society of General Physiologists will hold its annual meeting in the Marine Biological Laboratory, Woods Hole, Mass. The Medford meetings will open Tuesday with a teaching course, "The Teaching of Fluids, Electrolytes and Acid-Base" (1:30-7:30 p. m.). For the joint sessions, 351 papers have been scheduled.

Southwestern Surgical Congress.—The seventh annual meeting of the Southwestern Surgical Congress (originally scheduled a week later) will convene Sept. 5-7 at the Hotel Muehlebach, Kansas City, Mo. The guest speakers will include Drs. William P. Longmire Jr., Los Angeles; Frederick L. Reichert, San Francisco; and J. Englebert Dunphy, Boston, each of whom will serve as moderator of a panel discussion. On successive days an illustrated program will be presented by St. Louis University School of Medicine, University of Kansas School of Medicine, Kansas City, and Washington University School of Medicine, St. Louis.

Deputy Director of Mental Treatment Wanted.—The California State Department of Mental Hygiene will soon appoint a deputy director for hospital medical services (headquarters in Sacramento), to be in full charge of its treatment program, which serves 44,722 patients in 14 hospitals. Applications will be accepted through the State Personnel Board, 801 Capitol Ave., Sacramento, until Sept. 6. The position pays $1,250 a month salary to start, with increases to $1,350. The deputy director is responsible for organizing and coordinating the medical, psychiatric, and allied treatment programs of the 14 state hospitals for the mentally ill and mentally deficient. Applicants must have a certificate in psychiatry or mental hospital administration, or be eligible for such a certificate, and have three years' administrative experience in medicine and psychiatry. Selection will be made after a civil service examination in Sacramento Sept. 27.

Fulbright Lecturers Needed in Italy.—The Conference Board of Associated Research Councils, Committee on International Exchange of Persons, announces that the universities of Turin and Padua would welcome a lecturer for one term in one aspect of medicine or surgery. At Padua there is special interest in the use of radioactive isotopes in physiopathological and clinical investigations of blood diseases. A knowledge of Italian is essential. These openings refer to applications for awards under the 1956-1957 program for Italy under the Fulbright Act. Announcement is also made of the establishment of a National Institute for Nutrition in Rome by the Italian Research Council. The institute, affiliated with the University of Rome and said to have excellent equipment and facilities, proposes to expand its research on biological and social aspects of nutrition and would welcome the cooperation of an American specialist.

American Fracture Association.—The 16th annual meeting of the American Fracture Association will be held at the Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22, under the presidency of Dr. Henry W. Meyerding, Rochester, Minn. Speakers will include Drs. Harrison L. McLaughlin and Walter D. Ludlum Jr., New York; John Royal Moore and Anthony F. DePalma, Philadelphia; Earl D. McBride, Oklahoma City; Peter B. Wright, Augusta, Ga.; I. William Nachlas, Baltimore; John B. Erich, Rochester, Minn.; and Arthur H. Weiland, Miami, Fla. A dinner dance has been scheduled for Monday evening, a two hour water cruise for Tuesday afternoon, and the annual banquet (dress optional) for Wednesday evening. The association is planning a postconvention tour to Havana, Cuba, where a clinical program will be presented Sept. 26-27. For information, communicate with Dr. Herman W. Wellmerling, Secretary-General, 610 Griesheim Bldg., Bloomington, Ill.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Cancer Society Offers Clinical Fellowships.—The American Cancer Society announces to (1) editors of professional journals in general medicine and in specialties, (2) executive officers of teaching institutions approved by the Council on Medical Education and Hospitals of the American Medical Association, (3) coordinators of cancer teaching programs in medical schools, and (4) chiefs of service who are now, or who have been, directly responsible for training of American Cancer Society clinical fellows the availability of clinical fellowships for the next institutional year, July 1, 1956, to June 30, 1957. Applicants must be graduates of class A medical schools in the United States, its territories, or Canada, not be over 40 years of age, and be citizens of the United States. The annual stipend of clinical fellows of the American Cancer Society is $3,600. Application for one or more fellowships should be addressed to Dr. Brewster S. Miller, American Cancer Society, 521 W. 57th St., New York 19, via the executive officer of the institution. The deadline for filing applications is Sept. 15.

Meeting of Biological Photographic Association.—The 25th anniversary meeting of the Biological Photographic Association will be held at the Wisconsin Hotel, Milwaukee, Aug. 30-Sept. 2. Dr. John S. Hirschboeck, dean, Marquette University School of Medicine, Milwaukee, will deliver the address of welcome. The Tuesday afternoon program will include:

Aims and Program of the Medical Audio-Visual Institute, Mr. J. Edwin Foster, director, Medical Audio-Visual Institute.

Color Television in Medicine, Lieut. Stephen Dittman, M.S.C., medical audio-visual department, Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D. C.

Television broadcast from WTMJ-TV on "Armed Forces Institute of Pathology, Medical Illustration Service," Herman Van Cott, Washington, D. C. (broadcast to be picked up by RCA color receivers at convention).

RCA Color Television Demonstration, discussion by Mr. L. E. Flory, David Sarnoff Research Center, Princeton, N. J.

A tour of the General Electric X-Ray Corporation, Wednesday, will precede luncheon in the Brooks Memorial Union, with Marquette University as host. The guest speaker will be the Very Reverend Edward J. O'Donnel, S.J., president, Marquette University. After a tour of new University Libraries, Thomas S. Jones, A.B., professor emeritus of medical and dental illustration, University of Illinois College of Medicine, Chicago, will present "The Photographer's Responsibility in Medical Education," and Dr. G. Kasten Tallmadge, professor of the history of medicine, Marquette University School of Medicine, will discuss "Influence of the Fine Arts in Medical Illustration." The Thursday session will open at 9 a. m. with a symposium on medical movie-making. Dr. Joseph M. Lubitz, Wood, Wis., guest speaker at luncheon, will have as his subject "The Role of Medical Illustration in the Hospitals." The Eastman Kodak Company will be host at the cocktail hour preceding the awards banquet, at which Ralph Creer, Secretary, A. M. A. Committee on Medical Motion Pictures, will present "Horizons Unlimited." Information may be obtained from Leo Massopust, Marquette University School of Medicine, general chairman of the meeting.

FOREIGN

International Meeting on Military Medicine.—The International Congress of Military Medicine and Pharmacy will be held in Istanbul, Turkey, Aug. 28-Sept. 1. Questions to be considered include: Protection of Health Services During War; Recruiting Crisis in the Health Services of Armies; and Instruction in the Schools of the Health Services. The International Committee of Military Medicine and Pharmacy has announced that the 15th International Congress of Military Medicine and Pharmacy will meet in Buenos Aires, Argentina, in October, 1956. Questions to be considered at that meeting will include: Medical Services in Armored and Motorised Operations; Reduction of Noise in the Armed Forces; Radiation Defense in Military Medicine; Relations Between the Command of the Troops and Medical Services; and Study of the International Nomenclature of Medicaments Used by the Armed Forces and of an International Military Pharmaceutical Formulary.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

American Medical Association Public Relations Institute, Drake Hotel, Chicago, Aug. 31- Sept. 1. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

Academy of Psychosomatic Medicine, Hotel Plaza, New York, Oct. 6-8. Dr. Ethan Allan Brown, 75 Bay State Road, Boston 15, *Secretary.*

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 3-6. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Executive Secretary.

American Association of Medical Record Librarians, LaSalle Hotel, Chicago, Oct. 3-7. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association of Obstetricians and Gynecologists, The Homestead, Hot Springs, Va., Sept. 8-10. Dr. Frank R. Lock, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American College of Hospital Administrators, Convention Hall, Atlantic City, N. J., Sept. 17-19. Mr. Dean Conley, 620 North Michigan Ave., Chicago 11, Executive Director.

American Congress of Physicial Medicine and Rehabilitation, Hotel Statler, Detroit, Aug. 28-Sept. 2. Dr. Frances Baker, 30 North Michigan Ave., Chicago 2, Secretary.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 10, Director.

American Medical Writers' Association, Jefferson Hotel, St. Louis, Sept. 30-Oct. 1. Dr. Harold Swanberg, P.O. Drawer 110, Quincy, Ill., Secretary.

American Physiological Society Fall Meeting, Tufts College, Medford, Mass., Sept. 6-9. Dr. Allan C. Burton, Univ. of Western Ontario, London, Ont., Canada, Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-23. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Plastic and Reconstructive Surgery, Atlantic City, N. J., Sept. 25-30. Dr. Kenneth L. Pickrell, Duke Hospital Durham, N. C., Secretary.

Association of American Physicians and Surgeons, Chicago, Oct. 7-8. Mr. Harry E. Northam, 185 N. Wabash Ave., Chicago 1, Executive Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 594, Newark, N. J., Secretary.

Biological Photographic Association, Wisconsin Hotel, Milwaukee, Aug. 30-Sept. 2. Miss Jane H. Waters, Box 1668, Grand Central P.O., New York 17, Executive Secretary.

Central Association of Obstetricians and Gynecologists, Deshler-Hilton Hotel, Columbus, Ohio, Oct. 5-8. Dr. Edwin J. DeCosta, Suite 602, 116 S. Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, The Broadmoor, Colorado Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Boulevard, Galveston, Tex., Seceretary.

Clinical Orthopaedic Society, Skirvin Hotel, Oklahoma City, Sept. 30-Oct. 1. Dr. Marcus J. Stewart, 869 Madison Ave., Memphis, Tenn., Executive Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Delaware, Medical Society of, Delaware Academy of Medicine, Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware Ave., Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N.W., Washington 6, D. C., Executive Director.

Indiana State Medical Association, French Lick Springs Hotel, French Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Sept. 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Texas, Chairman.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 3-6. Dr. W. M. Kitchen, 306 E. Twelfth St., Kansas City 6e, Mo., Secretary.

Kentucky State Medical Association, Louisville, Sept. 27-29. Mr. J. P. Sanford, 620 S. Third St., Louisville, Executive Secretary.

Michigan State Medical Society, Pantlind Hotel, Grand Rapids, Sept. 26-30. Dr. L. Fernald Foster, 606 Townsend St., Lansing 5, Secretary.

Midwest Conference on Rheumatic Diseases, Henry Ford Hospital, Detroit, Oct. 5. Dr. J. J. Lightbody, 7338 Woodward Ave., Detroit 2, Medical Director.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Sept. 28-30. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Mississippi Valley Trudeau Society, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

Montana Medical Association, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

New England Health Institute, Colby College, Waterville, Me., Aug. 30-Sept. 1. Dr. Edward W. Colby, City of Portland Health Dept., Portland, Me., Chairman.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Tex., Sept. 17. Dr. E. C. Bebb, Broad St., Wichita Falls, Tex., Chairman.

Oregon State Medical Society, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Catter, 1020 S.W. Taylor St., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Postgraduate Assembly in Endocrinology and Metabolism, Indianapolis, Sept. 26-Oct. 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

Regional Meetings, American College of Physicians:

Jamestown, N. D., Sept. 10. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

Madison, Wis., Oct. 15. Dr. Howard Wakefield, 122 S. Michigan Ave., Chicago 3, Governor.

Society of General Physiologists, Marine Biological Laboratory, Woods Hole, Mass., Sept. 9-10. Dr. A. M. Shanes, National Institutes of Health, Bethesda 14, Md.

Southwestern Surgical Congress, Muehlebach Hotel, Kansas City, Mo., Sept. 5-7. Dr. C. M. O'Leary, 207 Plaza Court Bldg., Oklahoma City, Secretary.

Tennessee Valley Medical Assembly, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

U. S. Chapter, International College of Surgeons, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Union Bldg., Salt Lake City, Sept. 8-10. Mr. H. Bowman, 42 S. Fifth East St., Salt Lake City 2, Executive Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. Dr. James P. Hammond, 337 South St., Bennington, Secretary.

Virginia, Medical Society of, Hotel Jefferson, Richmond, Oct. 16-19. Mr. Robert I. Howard, 105 West Franklin St., Richmond, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

Western Association of Railway Surgeons, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

FOREIGN AND INTERNATIONAL

Canadian Society for the Study of Fertility, Royal York Hotel, Toronto, Ont., Canada, Oct. 6-8. Dr. Earl R. Plunkett, 469 Waterloo St., London, Ont., Canada, Secretary.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society for Research on Anesthesia, Miami Beach, Fla., U.S.A., Mar. 12-15, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of International Union of Railway Medical Services, Dubrovnik, Yugoslavia, Sept. 19-24. Dr. Jovanovic, Head Office, Yugoslav Railway, Belgrade, Yugoslavia, President.

Congress of International Union Against Venereal Diseases, Naples, Italy, Sept. 25-28. For information address: Prof. Monacelli, University of Naples, Dept. of Dermatology, Naples, Italy.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

International Academy of Legal and Social Medicine, Plenary Conference, Genoa, Italy, Oct. 13-17. Prof. Domenico Macaggi, Institut de Medicine legale, Universite de Genes, Genes, Italy, President.

International Conference of Medical Librarians and Reference Librarians, University Hall, Brussels, Belgium, Sept. 10. For information address: Miss Ch. de Looze, Librarian % Oeuvre Nationale Belge de Defense contra la Tuberculose, 56, rue de la Concorde, Brussels, Belgium.

International Congress of Allergology, Rio de Janeiro, Brazil, S. A., Nov. 6-13. Dr. Bernard N. Halpern, 197 boulevard St. Germain, Paris 7^{e}, France, Secretary General.

International Congress of Angiology and Histopathology, Fribourg, Switzerland, Sept. 2-5. For information write: Dr. Gerson, 4 rue Pasquier, Paris 8^{e}, France.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress of Criminology, London, England, Sept. 11-18. For information write: Dr. Carroll, 28 Weymouth St., London, W.1, England.

International Congress of European Society of Haematology, Freiburg i,Br., Germany, Sept. 20-24. Prof. Dr. L. Heilmeyer, Hugstetter Strasse 55, Freiburg i,Br., Germany, Chairman.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of International College of Surgeons, Buenos Aires, Argentina, S. A., Nov. 19-24, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of International Society of Bronchoesophagology, Buenos Aires, Argentina, S. A., Oct. 28-29. Dr. Juan Carlos Arauz, Cangallo 4015, Buenos Aires, Argentina, S. A., Secretary General.

International Congress of Librarianship and Documentation, Brussels, Belgium, Sept. 11-18. For information write: Dr. A. C. Breycha-Vauthier, Librarian, United Nations, Geneva, Switzerland.

International Congress of Medical Professional Jurisdiction, Medical Ethics, and Comparative Medical Law, Paris, France, Sept. 30-Oct. 3. Dr. J. R. DeBray, Conseil National de L'Ordre des Medécins, 60, Boulevard Latour-Maubourg, Paris 7e, France, Secretary General.

International Congress of Military Medicine and Pharmacy, Istanbul, Turkey, Aug. 28-Sept. 1. Dr. J. Voncken, International Committee of Military Medicine and Pharmacy, 79 rue Saint Laurent, Liege, Belgium, *Secretary-General*.

International Congress of Neo-Hippocratic Medicine, Montecatini, Terme, Italy, May 20-22, 1956. Prof. P. Delore, 13 rue Jarente, Lyon, France, Secretary-General.

International Congress of Neuropathology, London, England, Sept. 12-17. Dr. W. H. McMenemey Maida Vaie Hospital for Nervous Diseases, London, W.9, England, Secretary.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, Mexico, Secretary General.

International Congress on Urinary Lithiasis, Evian, France, Sept. 2-4. Mr. Rossollin-Grandville, Direction Cachet, Evian (Hte-Savoie), France, Secretary General.

International Congress of World Confederation for Physical Therapy, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International General Medical Congress, University of Rosario Medical College, Rosario, Argentina, S. A., Nov. 7-12. Dean Jose Imhoff, Santa Fé 3100, Rosario, Argentina, S. A., Chairman.

International Medical Congress, Verona, Italy, Sept. 1-4. For information write: c/o Offices of the International Verona Fair, Piazza Bra., Verona, Italy.

International Office of Documentation of Military Medicine, Istanbul, Turkey, Aug. 28-Sept. 1. Dr. J. Voncken, 79 rue Saint Laurent, Liege, Belgium, Secretary-General.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Society for the Study of Biological Rhythms, Stockholm, Sweden, Sept. 15-17. For information write: Prof. Ture Petrén, Karolinska Institutet, Stockholm 60, Sweden.

International Vitamin E Congress, Cini Foundation, Island of San Giorgio Maggiore, Venice, Italy, Sept. 5-8. Prof. Emilio Raverdino, via Pietro Verri 4, Milano, Italy, Secretary.

Neuroradiologic Symposium, London, England, Sept. 13-17. Dr. R. D. Hoare, National Hospital, Queen Square, London, W.C.1, England, Secretary.

Pan American Congress of International College of Surgeons, Mendoza City, Argentina, S. A., Oct. 22-26. For information address: Secretary, Caseros Av. 2154, Buenos Aires, Argentina, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Medical Social Convention, Bogota, Colombia, S. A., Oct. 15-22. Dr. Leopoldo E. Araujo, Avenida de los Presidentes Num. 506, Apartado 2589, La Habana, Cuba, Secretary.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

Venezuelan Congress of Medical Sciences, Caracas, Venezuela, S. A., Nov. 18-26. Dr. A. L. Briceno Rossi, Apartado 4412, Ofic. del Este, Caracas, Venezuela, S. A., Secretary General.

World Congress of Anesthesiologists, Scheveningen, Netherlands, Sept. 5-10. For information write: Mr. W. A. Fentener van Vlissingen, Noord-Houdringelaan, 24, Bilthoven, Netherlands.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

World Medical Association, Vienna, Austria, Sept. 20-26. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination*. Montgomery, June 19-21. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Arizona:* *Examination*. Phoenix, Oct. 12-14. *Reciprocity*. Phoenix, Oct. 15. Exec. Sec., Mr. Robert Carpenter, 411 Security Bldg., Phoenix.

Arkansas:* *Examination*. Little Rock, Nov. 10-11. Sec., Dr. Joe Verser, Harrisburg.

California: *Written*. Los Angeles, Aug. 22-25; and Sacramento, Oct. 17-20. *Oral and Clinical Examinations for Foreign Medical School Graduates*. Los Angeles, Aug. 21; and San Francisco, Nov. 13. *Oral Examination for Reciprocity Applications*. Los Angeles, Aug. 20; and San Francisco, Nov. 12. Sec., Dr. Louis E. Jones, Room 536, 1020 N St., Sacramento.

Colorado:* *Examination*. Denver, Dec. 6-7. Final date for filing application is Nov. 4. *Reciprocity*. Denver, Oct. 11. Final date for filing application is Sept. 12. Exec. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination*. Hartford, Nov. 8-10. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic*. Derby, Nov. 8-19. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination*. Dover, Jan. 10-12. *Reciprocity*. Dover, Jan. 19. Sec., Dr. Joseph S. McDaniel, Dover.

Florida:* *Examination*. Miami Beach, Nov. 20-21. Sec., Dr. Homer L. Pearson, 901 N. W. 17th St., Miami.

Georgia: *Examination*. Atlanta, Oct. 5-6. *Reciprocity*. Atlanta, Oct. 7. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Idaho: *Examination and Reciprocity*. Boise, Jan. 9-11. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity*. Chicago, Oct. 11-13. Supt. of Registration, Mr. Fredric B. Selcke, State House, Springfield.

Indiana: *Examination*. Indianapolis, June. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Kansas: *Examination and Endorsement*. Topeka, Dec. 7-8. Sec., Dr. Lyle F. Schmaus, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination*. Louisville, Dec. 5-7. Asst. Sec., Mr. R. F. Dixon, 620 S. 3rd St., Louisville.

Maine: *Examination and Reciprocity*. Portland, Nov. 8-9. Sec., Dr. Adam P. Leighton, Portland.

Maryland: *Examination*. Baltimore, Dec. 13-16. Exec. Sec., Miss Hannah A. McCarthy, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination*. Lansing, Oct. 12-14. Sec., Dr. J. Earl McIntyre, 118 Stevens T. Mason Bldg., Lansing.

Minnesota:* *Examination and Reciprocity*. Minneapolis, Oct. 18-20. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity*. Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Montana: *Examination and Reciprocity*. Helena, Oct. 4-5. Sec., Dr. Sidney A. Cooney, 7 West 6th Ave., Helena.

Nebraska:* *Examination*. Omaha, June 18-20. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* *Examination and Reciprocity*. Reno, Oct. 4. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Reciprocity*. Concord, Sept. 14. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination*. Trenton, Oct. 18-21. Sec., Dr. Patrick H. Corrigan, 28 W. State St., Trenton.

New Mexico:* *Examination and Reciprocity*. Santa Fe, Nov. 21-22. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

New York: *Examination*. Albany, Buffalo, New York City and Syracuse, Oct. 4-7. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity*. Asheville, Oct. 31. Sec., Dr. Jos. J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination*. Grand Forks, Jan. 4-6. *Reciprocity*. Grand Forks, Jan. 7. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Reciprocity*. Columbus, Oct. 4. *Examination*. Columbus, Dec. 15-17. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* *Endorsement*. Oklahoma City, Sept. 4. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Reciprocity*. Portland, Oct. 13-15. *Examination*. Portland, January. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination*. Philadelphia, January. Acting Sec., Miss Marguerite G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination*. Providence, Oct. 6-7. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Tennessee:* *Examination*. Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Virginia: *Examination*. Richmond, Dec. 7-9. *Reciprocity*. Richmond, Dec. 6. Final date for filing application is Nov. 21. Address the Secretary, 631 First St. S.W., Roanoke.

WEST VIRGINIA: *Reciprocity*. Charleston, Oct. 10. Sec., Dr. N. H. Dyer, Charleston 5.

WISCONSIN:* *Reciprocity*. Madison, Oct. 21. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

WYOMING: *Examination*. Cheyenne, Oct. 3. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

ALASKA:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: *Examination*. Tucson, Sept. 20. Sec., Dr. H. D. Rhodes, University of Arizona, Tucson.

ARKANSAS: *Examination*. Little Rock, Oct. 4. Sec., Dr. S. C. Dellinger, Zoology Dept., University of Arkansas, Fayetteville.

COLORADO: *Examination*. Denver, Sept. 7-8. Final date for filing application is Aug. 24. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

CONNECTICUT: *Examination*. New Haven, Oct. 8. Address: State Board of Healing Arts, 258 Bradley St., New Haven 10.

DISTRICT OF COLUMBIA: *Examination*. Washington, Oct. 24-25. Deputy, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington 6.

FLORIDA: *Examination*. Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, Box 340, Gainesville.

IOWA: *Examination*. Des Moines, Oct. 11. Sec., Mr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination and Endorsement*. Detroit and Ann Arbor, Oct. 14-15. Sec., Mrs. Anne Baker, 410 W. Michigan Ave., Lansing 15.

MINNESOTA: *Examination*. Minneapolis, Oct. 4-5. Sec., Mr. Raymond N. Bieter, 126 Millard Hall, University of Minnesota Campus, Minneapolis.

NEBRASKA: *Examination*. Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Examination*. Reno, Oct. 4. Sec., Dr. Donald G. Cooney, Box 9005, University of Nevada, Reno.

OKLAHOMA: *Examination*. Oklahoma City, August 26-27. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination*. Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

TENNESSEE: *Examination*. Memphis, Sept. 22-23. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

TEXAS: *Examination*. Austin and Houston, Oct. 21-22. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

WISCONSIN: *Examination*. Madison, Sept. 23; Milwaukee, Dec. 3. Sec., Mr. William H. Barger, 621 Ransom St., Ripon.

ALASKA: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity*. On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Aug. 29

NBC-TV, 9 p. m. EDT. "Medic" again takes up the role medicine would play after an atomic attack in the rerun of "Flash of Darkness."

Tuesday, Aug. 30

CBS-TV, 10:30 p. m. EDT. "The Search" presents the second of two reports from Tulane University entitled "New Hope for the Mentally Ill."

Wednesday, Aug. 31

NBC-TV, 11 a. m. EDT. "Medical and Health News with Howard Whitman," a feature on the daily "Home" program, reports on activities of the American Medical Association in a special pickup from Chicago.

MAGAZINES

Saturday Evening Post, Aug. 20, 1955

"Let Those Crash Victims Lie!" by Greer Williams

"The damage that may be done to a fractured leg or spine because of ignorant handling is often greater than that of the initial accident," says Dr. Robert H. Kennedy, former chairman of the American College of Surgeons' Committee on Trauma. The article points out that: "If you're hurt on the highway, there's a three-in-ten chance you'll be mishandled before you reach the hospital" and recommends that crash victims be permitted to lie until expert help arrives. The author also mentions the dangers involved in rushing accident cases to the hospital at excessive speeds. He says: "Thirty-five miles an hour is generally regarded as fast enough for transporting patients."

Parade, Aug. 28, 1955

"The Boy Who Feels No Pain"

A report from Pembury, Kent, England, about a boy with a condition called ganglioneuropathy. "Something is wrong with the ganglia (nerve centers) which carry the sensation of pain to the brain." He must wear special padded clothing to protect him from injury and is kept home from school because children kick and punch him to verify his malady.

Reader's Digest, September, 1955

"How It Feels to Have a Heart Attack," by Robert Wallace

Condensation of a *Life* article which tells in a dramatic, narrative fashion how it feels to suffer a heart attack.

"Cancer and a Woman's Sex," by Emerson Day, M.D.

A cancer specialist answers questions asked by women on the relationship between her sex and cancer. Originally a *Woman's Home Companion* article.

"Medical Sleuth Extraordinary," by Paul de Kruif

"Good general practitioners are often keen diagnosticians, but sometimes they are stumped by unusually enigmatic cases. Then they're likely to ask help from doctors called internists, the detectives of the medical profession." In an article condensed from *Today's Health*, Mr. de Kruif explains the functions of an internist and tells how a physician obtains certification from the American Board of Internal Medicine.

"Hospitals Are Everybody's Business," by Elsie McCormick

Industry's Advisory Board for Hospitals has 200 experts ready to give free advice on time and labor-saving methods to hospitals in the Raritan Valley area of New Jersey. Chapters of the Society for the Advancement of Management have hospital-aid committees in operation in various towns, and similar work is being done by the American Institute of Industrial Engineers. (Condensed from *The American Mercury*)

"Things to Know About Sleep," by Blake Clark and Norman Dine

A series of questions and answers on the subject of sleep including "why do we sleep," "how much sleep is normal," "is snoring curable." The original article appeared in *Your Life*.

Better Homes and Gardens, September, 1955

"New Victories Predicted for Medicine!" by Donald G. Cooley

The author reports on scientific material presented at the American Medical Association's annual meeting in Atlantic City. "Family doctors and specialists shared knowledge, brought each other up-to-date on latest advances in medicine and surgery and went home to get a running start on brilliant advances in medical science forecast for the next half century."

Ladies' Home Journal, September, 1955

"Let's Stop Killing and Crippling Our Children," by Harry F. Dietrich, M.D., and Barbara Berch Jamison

"Between 11,000 and 13,000 children are killed in this country every year and 40,000 to 50,000 other children are permanently crippled and disabled—'by accident.'" The article urges a combination of preventive measures and an educational program to help reduce the number of accidents caused by burning, drowning, poisoning, falls, crushing, and "automotive mayhem."

DEATHS

O'Leary, Paul Arthur ⊕ Rochester, Minn.; born in Brooklyn, N. Y., Nov. 11, 1891; Long Island College Hospital, Brooklyn, N. Y., 1915; interned at the Long Island College Hospital in Brooklyn; on Jan. 1, 1917, came to the Mayo Clinic as an assistant in dermatology and syphilology; in May, 1924, was appointed head of the section of dermatology and syphilology, retaining that post until July, 1953, when he became a senior consultant; in 1924 he was appointed professor of dermatology and syphilology in the Mayo Foundation for Medical Education and Research, a part of the Graduate School of the University of Minnesota; in 1951 president of the staff at the clinic; served during World War I; chairman of the Section on Dermatology of the American Medical Association, 1936-1937; in 1951 president of the Olmsted County Medical Society; past-president of the American Dermatological Association, Minnesota Dermatological Society, and the Chicago Dermatological Society; one of the founders, formerly vice-president, and second president of the American Academy of Dermatology and Syphilology; member of the Pan American Medical Association, New York Academy of Medicine, American Association for the Advancement of Science, Minnesota Academy of Science, Society for Investigative Dermatology, Minnesota Academy of Medicine, American Association of University Professors, Sigma Xi, Alpha Kappa Kappa, and Beta Theta Pi; corresponding member of several foreign societies; honorary member of the Royal Society of Medicine of England, British Association of Dermatologists, German Dermatological Society, Berlin Dermatological Society, Dutch Society of Dermatology and Syphilology, the Hellenic Antivenereal Society of Greece, the Manhattan Dermatological Society, and the Dallas Dermatological Society; in 1950 made an honorary member of Alpha Omega Alpha; fellow of the American College of Physicians; in 1940 secretary-general of the 10th International Congress on Dermatology and Syphilology; specialist certified by the American Board of Dermatology and Syphilology and served as a member of the board from 1938 to 1948; in 1939 appointed a member of the National Advisory Health Council; served also as chairman of the dermatoses investigative committee of the U. S. Public Health Service; editor-in-chief of *Archives of Dermatology and Syphilology* since 1947; associate editor of *American Journal of Syphilis, GP, Der Hautarzt, Dermatologica,* and *Excerpta Medica, Section XIII;* dermatological editor of "Current Therapy" and of "The Book of Health"; collaborated with Dr. John H. Stokes on "Modern Clinical Syphilology"; the *Journal of Investigative Dermatology* honored him by dedicating its March, 1954, issue to him; on the staff of the Rochester Methodist Hospital and St. Mary's Hospital, where he died July 20, aged 64, of cancer of the pancreas.

Heusinkveld, David William ⊕ Cincinnati; born in Fulton, Ill., July 17, 1897; Rush Medical College, Chicago, 1925; in 1934 appointed to the faculty of the University of Cincinnati College of Medicine, where at the time of his death he was assistant clinical professor of medicine; president of the Ohio State Medical Association and for five years served as councilor of the First District; on Feb. 16, 1939, was elected to the board of the Anti-Tuberculosis League, and served this organization in various capacities from that time until his death, when he was Christmas Seal committee chairman, a post he had held for eight years; member of the executive and finance committees and of the medical and programming committees; president of the Anti-Tuberculosis League from 1945 to 1948; member of the American College of Chest Physicians and served on the board of governors of that organization since 1950; president of the Ohio Tuberculosis and Health Association, 1953-1954; past-president of the Academy of Medicine of Cincinnati; charter member of the Ohio Trudeau Society; member of the National Tuberculosis Association and of the American Trudeau Society; in 1949 appointed to the board of trustees of Hospital Care Corporation for Southwestern Ohio, in 1950 vice-president, and in 1952 president; served on the executive committee from 1950; from 1950 to 1952 was on the board of directors of the Cincinnati Chamber of Commerce; roentgenologist for the Cincinnati and Hamilton County health departments; commissioned a second lieutenant in the infantry during World War I; director of chest service in the Good Samaritan Hospital; on the staffs of Bethesda and Dunham hospitals; died in Columbus June 25, aged 57, of a heart attack.

Baketel, H. Sheridan ⊕ St. Davids, Pa.; born in Hopedale, Ohio, Nov. 15, 1872; Dartmouth Medical School, Hanover, N. H., 1895; did postgraduate work at Harvard, and in London and Paris; in 1915 became lecturer in medical economics at the Long Island College Hospital in Brooklyn, N. Y., now known as the State University of New York College of Medicine at New York City, serving as professor of preventive medicine and hygiene from 1915 to 1931, when he became professor emeritus; served during World War I; became a colonel in the Medical Reserve Corps in 1924 and retired in 1949; chairman of the board of trustees at Columbia University College of Pharmacy in New York City from 1938 to 1942; president of the physiological laboratories of Reed and Carnrick of Jersey City and chairman of the Reed and Carnrick Institute for Medical Research; delegate to the U. S. Pharmacopeia Convention from 1930 to 1940; fellow of the American College of Physicians, American Public Health Association, and the New York Academy of Medicine; past-president of the American Medical Editors' Association and the American Pharmaceutical Manufacturing Association; life member of the American Urological Association; member of the Sons of the American Revolution and the Military Order of the World War; past-president of the Dartmouth Medical Alumni Association and past vice-president of Beta Theta Pi; consultant at the Peekskill (N. Y.) Hospital; author of "Treatment of Syphilis"; cofounder and editor-in-chief of *Medical Economics;* at one time editor of the *Medical Times;* died July 7, aged 82, of coronary disease.

Rosenthal, Nathan ⊕ New York City; born in New York City March 14, 1890; Columbia University College of Physicians and Surgeons, New York City, 1913; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists; formerly associate clinical professor of medicine at his alma mater; in 1953 received the first Harlow Brooks medal for research in hematology at the New York Academy of Medicine; founder-member and past-president of the Society for the Study of Blood; member of the Harvey Society, New York Academy of Medicine, and other professional groups; during World War I served at the United States Base Hospital No. 3 in southern France; at one time associate editor of *Blood—The Journal of Hematology;* consulting hematologist at the St. Joseph Hospital in Far Rockaway, Long Beach (N. Y.) Memorial Hospital, Methodist Hospital in Brooklyn, French Hospital, Beth David Hospital, Bronx Hospital, and Harlem Hospital; founder of the hematology laboratory and consulting hematologist at Mount Sinai Hospital, where he served as an intern, research fellow, and chief of the medical clinic, and where he died June 29, aged 65.

Maynard, Carl Wesley ⊕ Pueblo, Colo.; born in 1886; Northwestern University Medical School, Chicago, 1910; specialist certified by the American Board of Pathology; member and past-president of the American Society of Clinical Pathologists; past-president of the Pueblo County Medical Society; fellow of the College of American Pathologists; a charter member and a life member of the Colorado State Pathological Society, which on June 4, 1955, awarded him a distinguished service scroll; consultant and in charge of laboratory at Mennonite Hospital and Sanitarium in La Junta; one of the original founders of the Pueblo Clinic and in charge of the department of pathology; on the consulting staff of Colorado State Hospital; on the staffs of St. Mary Hospital and the Parkview Episcopal Hospital, where he died June 15, aged 68, of rheumatic heart disease.

⊕ Indicates Member of the American Medical Association.

Jones, Harold Houston Sr. ⊕ Winfield, Kan.; born in Viele, Iowa, in 1891; Washington University School of Medicine, St. Louis, 1915; specialist certified by the American Board of Internal Medicine; member of the American Trudeau Society; member of the board of regents and ex-governor of the American College of Physicians; lecturer, Graduate School, University of Kansas; member of the medical advisory board, National Multiple Sclerosis Society; director of research, H. L. Snyder Memorial Research Foundation; served during World War I and was awarded the Silver Star medal; on the staffs of the William Newton Memorial and St. Mary's hospitals; died May 30, aged 63, of chronic bronchitis, emphysema, and pneumothorax.

Ryerson, Frank Leith ⊕ Detroit; Detroit College of Medicine, 1911; assistant professor of clinical ophthalmology at his alma mater, now known as the Wayne University College of Medicine; specialist certified by the American Board of Otolaryngology; an associate member of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; on the staffs of the Shurly and Evangelical Deaconess hospitals, Eloise (Mich.) Hospital and Infirmary, and the City of Detroit Receiving Hospital; died in Harper Hospital April 3, aged 68, of arteriosclerotic heart disease.

Abbott, William Pitt, Grand Marais, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1906; died May 18, aged 74.

Acker, James Milton, Aberdeen, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1910; past-president of the Mississippi State Medical Association; served overseas during World War I; at one time superintendent of the Mississippi State Hospital; died July 9, aged 67.

Bunsick, Philip ⊕ Brooklyn; University and Bellevue Hospital Medical College, New York City, 1923; on the staffs of Madison Park Hospital of Adelphi College and Shore Road Hospital; died May 15, aged 54, of cancer.

Dobson, Richard Allen ⊕ New York City; Meharry Medical College, Nashville, Tenn., 1909; formerly practiced in Sioux City, Iowa, where he was on the courtesy staff of the Methodist, St. Vincent's, and St. Joseph Mercy hospitals; died May 25, aged 72, of carcinoma of the prostate.

Fawcett, John Thomas ⊕ Grand Rapids, Mich.; University of Toronto Faculty of Medicine, Toronto, Canada, 1924; served during World Wars I and II; formerly practiced in Elyria, Ohio, where he was on the staff of the Elyria Memorial Hospital; died in the Blodgett Memorial Hospital June 20, aged 59, of arteriosclerotic heart disease.

Fletcher, Oscar Richard, Sanford, Va.; University of Maryland School of Medicine, Baltimore, 1908; member of the Medical Society of Virginia; served as a member and secretary of the county board of health; president of the board, National Hallwood Bank; on the staff of Northampton-Accomack Memorial Hospital, Nassawadox, where he died June 14, aged 72, of cerebral hemorrhage with left-sided hemiplegia.

Freeman, Ralph Waldo ⊕ Fillmore, Utah; University of Illinois College of Medicine, Chicago, 1934; served during World War II; city physician; on the staff of Fillmore Latter-Day Saints Hospital; died in Salt Lake City June 23, aged 50, of coronary arteriosclerosis.

Gaff, John Henry, Chicago; St. Louis College of Physicians and Surgeons, 1907; died April 9, aged 73, of peritonitis, appendicitis, and diabetes mellitus.

Granberry, Howard Baldwin Jr. ⊕ Austin, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1926; on the staff of the student health center of the University of Texas; a member of the state board of health, serving a term as its chairman; on the staffs of the Brackenridge Hospital and the Holy Cross Hospital, where he died June 15, aged 55, of myocardial infarction.

Greear, Clabe Baker ⊕ Honaker, Va.; State University of Iowa College of Medicine, Iowa City, 1902; twice president of the Russell County Medical Society; a past member of the county board of health, and a member of the medical examining board and volunteer medical service board in World War I; died May 29, aged 78, of coronary occlusion.

Grimes, Loring ⊕ Swampscott, Mass.; Harvard Medical School, Boston, 1904; past-president of the South Essex Medical Society; during World Wars I and II served as a member of the Selective Service Board; for many years chairman of the board of health; past-president of the Swampscott Rotary Club; at one time associate medical examiner of Essex County; served as chief of the surgical staff at the Lynn Hospital, where he died June 19, aged 74, of heart disease.

Hahn, LeRoy Walter ⊕ Berkeley, Calif.; University of California Medical School, San Francisco, 1928; also a graduate in dentistry; member of the American Academy of General Practice; on the staff of the Alta Bates Community Hospital; died July 10, aged 58, of cerebral vascular accident, arteriosclerosis, and diabetes mellitus.

Hampton, Aubrey Otis ⊕ Washington, D. C.; Baylor University College of Medicine, Dallas, Texas, 1925; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, of which he was at one time vice-president, the Radiological Society of North America, and the American College of Radiology; formerly on the faculty of Harvard Medical School in Boston; served during World War II; died July 17, aged 54.

Hands, Edgar Beach ⊕ Shreveport, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1903; an associate member of the American Medical Association; on the staffs of the North Louisiana and T. E. Schumpert Memorial sanitariums; formerly member of the board of directors of the Shreveport Charity Hospital; for many years company physician for the Shreveport division of the Pullman Company; died June 24, aged 81, of carcinoma of the colon with metastases to the liver.

Hanner, George William, Montoursville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1925; died June 12, aged 55, of duodenal ulcer with obstruction and arthritis.

Hare, Jessie Blanch Daniells, Los Angeles; University of Michigan Medical School, Ann Arbor, 1887; died June 26, aged 93, of arteriosclerotic heart disease.

Hellwig, John William ⊕ Omaha; Creighton University School of Medicine, Omaha, 1901; member of the American Urological Association; served on the faculty of his alma mater; died June 16, aged 79.

Hill, James Fitts ⊕ Montgomery, Ala.; Columbia University College of Physicians and Surgeons, New York City, 1911; owner of the Fitts Hill Hospital; for a long time chairman of the board of the Union Bank and Trust Company; died June 27, aged 66, of tuberculosis.

Hyde, Frederick Wirt ⊕ Detroit; Detroit College of Medicine and Surgery, 1914; on the staff of the Delray General Hospital; died July 3, aged 66, of carcinoma of the pancreas.

Jewell, Joe Pell ⊕ Piedmont, S. C.; Medical College of the State of South Carolina, Charleston, 1913; served during World War I; died June 18, aged 66.

Joyce, Thomas Bernard, Carmel, N. Y.; Cornell University Medical College, New York City, 1920; physician for the New York Department of Labor, Workman's Compensation Courts; died June 11, aged 63, of coronary thrombosis due to arteriosclerosis.

Kress, Lauretta Eby ⊕ Orlando, Fla.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; an associate member of the American Medical Association; died June 28, aged 91, of cerebral thrombosis.

Leininger, Elmer Clyde ⊕ Chicago; Northwestern University Medical School, Chicago, 1911; on the staffs of the Grant and Henrotin hospitals; died in the Woodlawn Hospital, Rochester, Ind., July 11, aged 68, of coronary disease.

Leslie, Walter Logan ⊕ Russellville, Mo.; Washington University School of Medicine, St. Louis, 1906; died June 18, aged 75.

McCarty, Hiram George, Cleveland; St. Louis University School of Medicine, 1913; member of the Cleveland Academy of Medicine; director of St. Mary's Orphanage; on the staff of St. Ann's Maternity Hospital; for many years on the staff of St. Alexis Hospital, where he died July 11, aged 71, of cardiac decompensation.

McKee, George Lashell ⊕ Burgettstown, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1902; served on the staffs of the South Side and Mercy hospitals in Pittsburgh; died June 12, aged 77, of carcinoma of the stomach.

Mileau, Alexander Jr. ⊕ Major, U. S. Army, retired, San Antonio, Texas; Tufts College Medical School, Boston, 1916; served during World War I; retired Sept. 30, 1934; died in Brooke Army Hospital in Fort Sam Houston July 4, aged 65, of arteriosclerotic heart disease.

Miller, Frank Edward ⊕ Curtice, Ohio; Ohio State University College of Medicine, Columbus, 1917; member of the American Academy of General Practice; served during World War I; on the staffs of St. Vincent's Hospital, St. Luke's Hospital, Riverside Hospital, and St. Charles Hospital in Toledo, where he died July 12, aged 66, of heart disease.

Miller, William Anthony ⊕ New York Mills, Minn.; Kansas City (Mo.) Medical College, 1896; member of the school board; served on the board of health and as deputy coroner; on the staff of St. James Hospital in Perham; member of the board of directors of the Farmers and Merchants State Bank, of which he was vice-president and president; died June 1, aged 82, of uremia.

Munson, Louis Manning, Chicago; Rush Medical College, Chicago, 1910; on the staff of the Alexian Brothers Hospital; died in Alexian Brothers Hospital, Oshkosh, Wis., July 3, aged 70, of pulmonary embolism, fracture of left hip, and hypertensive heart disease.

Murphy, William Joseph ⊕ Milwaukee; Milwaukee Medical College, 1909; served during World War I; for many years examining physician for the state boxing commission; at one time on the faculty of Marquette University School of Medicine; member of the American Academy of General Practice; on the staff of the Misericordia Hospital, where he died June 13, aged 69, of coronary thrombosis.

Nielsen, Louis Bernhard ⊕ Honesdale, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; an associate member of the American Medical Association; for many years health director of Wayne County; formerly registrar of vital statistics for Wayne County; served on the Wayne County Draft Board during World War I; on the staff of the Wayne County Memorial Hospital; died June 11, aged 74, of carcinoma of the prostate and subacute bacterial endocarditis.

Pinkstaff, James Taylor, St. Louis; Barnes Medical College, St. Louis, 1897; died in the Jewish Hospital June 15, aged 82, of cardiovascular accident and arteriosclerotic heart disease.

Roach, Thomas Nelson, Royse City, Texas; Baylor University College of Medicine, Dallas, 1905; died March 8, aged 80.

Senturia, Ben Druze ⊕ Chicago; Washington University School of Medicine, St. Louis, 1923; served during World War II; on the staff of the Veterans Administration Hospital; died July 18, aged 56, of coronary occlusion.

Seymour, James Henry, San Francisco; Cooper Medical College, San Francisco, 1892; died in the Hahnemann Hospital July 2, aged 85, of adenocarcinoma.

Sharkey, Mary Ellen, Chicago; Jenner Medical College, Chicago, 1908; died in the Bethany Hospital July 2, aged 79, of arteriosclerosis.

Smith, Earl Rutter, Albany, N. Y.; Long Island College Hospital, Brooklyn, 1898; died April 19, aged 81, of heart disease.

Smith, L. Lyne ⊕ Louisville, Ky.; Hospital College of Medicine, Louisville, 1903; an associate member of the American Medical Association; served during World War I; on the staffs of St. Anthony Hospital, SS. Mary and Elizabeth Hospital and St. Joseph Infirmary, where he was past-president of the medical staff and where he died June 3, aged 78, of arteriosclerotic heart disease.

Spring, Gardiner, Salisbury, Md.; University of the City of New York Medical Department, New York City, 1895; died in the Peninsula General Hospital June 21, aged 95, of arteriosclerosis.

Tomlinson, Charles Creighton ⊕ Omaha; University of Nebraska College of Medicine, Omaha, 1908; professor of dermatology and syphilology emeritus at his alma mater; member of the American Dermatological Association and the American Academy of Dermatology and Syphilology; specialist certified by the American Board of Dermatology and Syphilology; on the staffs of the Clarkson and Methodist hospitals; died July 1, aged 70.

Toothaker, Thomas J., Onaga, Kan.; University Medical College of Kansas City, Mo., 1907; died in Wamego June 14, aged 74, of cerebral hemorrhage.

Vastine, John Hursh ⊕ Shamokin, Pa.; College of Physicians and Surgeons, Baltimore, 1894; an associate member of the American Medical Association; died June 29, aged 85.

Vest, Cecil Woods ⊕ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1908; fellow of the American College of Surgeons; on the staffs of the Cambridge-Maryland Hospital in Cambridge, Church Home and Hospital, Union Memorial and West Baltimore General hospitals; served as a member of the board of trustees of the Grinnell (Iowa) College; died July 3, aged 73.

Vogel, Philip ⊕ San Francisco; Rush Medical College, Chicago, 1936; interned at the Franklin Hospital, where he served a residency; served during World War II; died in St. Mary's Hospital June 15, aged 44.

Wheeler, Herbert Edward, Spokane, Wash.; Rush Medical College, Chicago, 1908; member of the Washington State Medical Association; fellow of the American College of Surgeons; interned at St. Luke's Hospital in Chicago; served during World War I; for a short time in 1928 police surgeon; division surgeon for the Great Northern Railroad; member of the staff of Sacred Heart Hospital, St. Luke's Hospital, and the Deaconess Hospital, where he died June 23, aged 72, of myocardial infarction.

Wilhite, Lee Roy ⊕ Perkins, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1916; past-president of the Payne County Medical Society and vice-president of the Oklahoma Academy of General Practice; for many years member of the school board; served during World Wars I and II; vice-president of the Payne County Bank; on the staff of the Municipal Hospital in Stillwater; died July 9, aged 59, of arteriosclerosis.

Williams, Lee Viley, Nicholasville, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1904; member of the Kentucky State Medical Association; died in Lexington May 24, aged 75, of heart disease.

Yoder, Robert Donald ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1928; assistant clinical professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; served during World War II; affiliated with the Veterans Administration Hospital, where he died June 16, aged 49, of coronary occlusion.

Zimmerman, Charles Leroy, Harrisburg, Pa.; Medico-Chirurgical College of Philadelphia, 1914; specialist certified by the American Board of Psychiatry and Neurology; at one time a physician in the Indian Service; formerly on the staff of the Danville (Pa.) Hospital; served on the medical staff of the Veterans Administration; at one time a medical examiner for the Pennsylvania and the Norfolk and Western railroads; died July 11, aged 66, of arteriosclerotic heart disease.

CORRECTION

Pendleton, Edward.—The obituary of Dr. Edward Pendleton (The Journal, June 25, 1955, page 682) was erroneous. The physician referred to was Dr. Edward W. Pendleton, a member of the American Medical Association and a resident of Grafton, W. Va., who graduated from Louisville (Ky.) Medical College in 1897 and died in the Veterans Administration Hospital in Roanoke, Va., April 1, aged 81, of intestinal obstruction.

FOREIGN LETTERS

AUSTRIA

Chronic Renal Insufficiency in Childhood.—At the meeting of the Society of Physicians in Vienna on May 6, Rupp and Swoboda reported on a girl, aged 7, with a high degree of growth deficiency and rachitic skeletal changes. The patient's serum revealed hyperphosphatemia, acidosis, and azotemia. Bilateral hydronephrosis was established as being the cause. Since the basic disease was beyond repair, symptomatic treatment of the azotemia, acidosis, and the rachitic disturbance of the bones was attempted. Despite the severity of the metabolic disturbance the use of intestinal irrigation, alkalization, and administration of calcium, vitamin B_6, and vitamin D_2 was successful in relieving symptoms. The disturbance of renal function that was also manifested by an isosthenuria concerning various electrolytes, however, remained unchanged.

Virus Hepatitis and Diabetes.—At the same meeting Königstein and Aichmair said that infectious hepatitis was found in 30.6% of 10,925 patients without, as compared to 8.6% of 4,992 patients with, diabetes mellitus. In epidemics of homologous serum jaundice, this disease was particularly common among patients with diabetes mellitus. The speakers emphasized the protracted course of hepatitis in diabetic patients, the large number of patients whose diabetes becomes worse in the course of hepatitis, and the possibility of a posthepatitic, nephrotic attack. When it was possible to omit parenteral therapy, it was omitted to reduce the risk of infectious hepatitis. Drug treatment consisted of administration of vitamins of group B, vitamin K, methionine, choline chloride, and occasionally desoxycorticosterone acetate and vitamin C. Parenteral therapy was practiced only in patients with liver insufficiency. In such patients, additional infusions of casein hydrolysates and duodenal irrigations proved effective. The diet was poor in fat, rich in protein, and the carbohydrate content was liberal.

Diagnosis of Cushing's Syndrome.—At the same meeting, Lachnit and Weis stated that differentiation between pituitary basophilism and adrenal cortical hyperfunction, the two types of Cushing's syndrome, is essential not only for theoretical reasons but also for the introduction of appropriate treatment. Resection of one and partial resection of the other adrenal for adrenal cortical hyperplasia is associated with the risk of early death or of late impairment that cannot be completely controlled by hormones. Determination of the corticotropin level in the plasma after adequate fractionation showed great variations, but it can be demonstrated in the spinal fluid using hypophysectomized rats as test animals. The fact that the spinal fluid, which is relatively poor in proteins, can be injected directly into the test animals is an advantage. If description of the methods used and tables giving a summary of patients studied are analyzed, it should be possible to differentiate between pituitary basophilism and adrenocortical hyperfunction.

Repository-Protoveratrine for Hypertension.—At the meeting of the Society of Physicians in Vienna on May 20, Dr. E. Hueber reported that he gave repository-protoveratrine by mouth to patients with advanced hypertension. These tablets make possible a slow, even absorption of the protoveratrine, by means of a specially prepared porous filter. With this new drug it is possible to keep patients with advanced hypertension free from complaints for a long time by giving them the drug once in the morning and occasionally in the evening, thus maintaining their blood pressure at decreased or even normal levels. The unpleasant side-effects of protoveratrine occur less frequently or may be completely absent when these repository tablets are used. It may be possible to give other substances, such as analgesics, hormones, and vitamins, in such tablets to obtain a repository effect, using them instead of injections or giving them once a day instead of two or three times daily.

Operation for Aortic Stenosis.—At the same meeting Heinert and Kaindl reported on a man, aged 33, who on March 22 was operated on successfully for aortic stenosis associated with severe calcification of the valves. The operation was performed transventricularly. The orifice of the aortic valve, which had been reduced to 3 mm. in diameter, was severed partly by sharp and partly by dull dissection. The subjective and objective results of the operation were satisfactory. Surgical valvulotomy is indicated chiefly in patients with progressive aortic stenosis that is characterized by the typical murmur, the missing second aortic sound, occasionally visible pulsation in the supraclavicular and suprasternal region, and lowered systolic pressure with reduced amplitude of the pulse. Such patients complain of abnormal fatigue, angina pectoris, palpitation, and attacks of dyspnea. The prognosis may be favorable when the involvement of the aortic valve is isolated, but a simultaneous mitral stenosis may be severed at the same operation. The administration of ganglion blocking agents for eight days in gradually reduced doses and, in addition, two to three daily injections of small amounts of strophanthin or of lanatoside C are recommended for after-treatment. Pleural effusion when it occurs must be aspirated cautiously.

Treatment of Chronic Ulcers with Trypsin.—At the same meeting, Dr. H. Bruck reported that a new approach has been tried in the treatment of chronic ulcers of the leg, because current methods require about four weeks before covering of the ulcer can even be attempted when a two stage procedure is used. With the use of a purified trypsin, cleaning of even a suppurative ulcer may be achieved within two to three days to such a degree that surgical treatment can be applied. After radical excision of the ulcer, its adjacent area, and its base and after a thorough hemostasis, the wound is exactly covered with small Thiersch's grafts about the size of postage stamps. Because of the smallness of the individual grafts, any hematoma that develops can easily drain and a complete take of the grafts is facilitated. Of the 32 patients treated by this method, the results were highly satisfactory in 28. A breakdown of the transplanted skin occurred in four patients, probably because the excision was not sufficiently radical.

Radioactive Iodine.—At the meeting of the Society of Physicians in Vienna on May 27, Dr. H. Vetter reported on a woman, aged 68, who suffered a spontaneous fracture of the shaft of the femur in September, 1953. In the course of nailing the fragments, a metastasis of thyroid carcinoma was found. After thyroidectomy the patient was given two doses, each of 100 mc., of radioactive iodine. In April, 1955, it was possible to remove the nail. Only a small proportion of patients with thyroid carcinomas can be successfully treated with radioactive iodine. In these patients, however, satisfactory results of long duration may be obtained. Roentgen treatment of carcinoma of the thyroid is indicated only after every attempt has failed to induce uptake of radioactive iodine by the cancer tissue.

Hormonal State and Multiple Sclerosis.—At the same meeting Birkmayer and his co-workers stated that, based on the observation that constitutionally manifest characteristics may accompany various types of evolution of multiple sclerosis, the excretion values of gonadotrophin, 17-ketosteroids, and estrin were determined in 24-hour samples of urine obtained from 71 patients with multiple sclerosis. The clinical course of the disease in the patients who showed deficient excretion of hormones with regard to their age and sex presented the following peculiarities: the duration of the disease was shorter than that in patients with normal excretion of hormones; the interval between the onset of the disease and the occurrence of complete paralysis was much shorter; and the number of patients who were not able to walk was significantly larger. The speakers concluded that a functionally normal hypophyseoadrenocortical axis causes a milder and longer course of multiple sclerosis and is associated

The items in these letters are contributed by regular correspondents in the various foreign countries.

with less functional disintegration. In those patients in whom the work capacity of the hypophyseoadrenocortical axis is insufficient as a result of constitutional or additional stress factors, functional disintegration occurs more rapidly and to a greater extent. These observations suggest that substitution therapy with implantation of hypophysin and administration of Percorten (desoxycorticosterone trimethylacetate) and Cortiron (desoxycorticosterone acetate) may be effective.

Nerve Transplantation.—Dr. W. Hartenau, addressing the Society of Physicians of Vienna on June 3, said that in treating a traumatic defect of the facial nerve only the restoration of its functional capacity produces a good result. This can be accomplished by decompression of the nerve, suture, or free transplantation. The chorda tympani of a 13-year-old patient was destroyed for a distance of about 7 mm. at the time of a tympanoplastic operation. An intratemporal plastic repair was performed 12 hours later, and the missing piece was replaced by a transplant from the cutaneus femoris lateralis nerve. Under a magnifying glass, this piece was adapted to the freshened ends without suture and was fixed in a bone groove. Four months later active movements of the muscles supplied by the oral branch of the nerve began. At the time of speaking the oral branch functioned well, the ophthalmic branch showed less function, and the branch innervating the forehead showed no function, but further improvement was expected.

BRAZIL

End of Malaria in Federal District.—Dr. S. Ferreira Pinto of the National Department of Health (*Revista Brasileira de Malariologia*) reports that there were no cases of malaria in the Federal District in 1954. Between 1942 and 1947, the combat against the vectors, Anopheles tarsimaculatis and A. albitarsis, was aimed exclusively at their aquatic forms. It was an exacting and costly fight yielding slow results and little progress, although, at the end of the sixth year of the campaign—in 1947—a reduction of about 60% in the incidence of the disease was noted. From 1948 on, when a single annual spraying of houses with chlorophenothane (DDT) was begun, a more rapid reduction occurred. In order to obtain the complete eradication of malaria in the Federal District and knowing that the seasonal period of transmission of the disease in the region lasts seven or eight months, beginning in 1952, two annual cycles of spraying were made. In that year, only seven cases of malaria were reported, followed by three in 1953 and none in 1954. According to the concept of malaria eradication set forth by the World Health Organization, three years without transmission of the disease are required before an endemic area is considered free from malaria. The author believes that, with the continued use of the measures described, the situation will be maintained for several more years.

Urinary Sediment.—Dr. A. V. Rotondi of São Paulo reported to the Associação Paulista de Medicina that in all of a series of 50 normal young men the quantitative urinary sediment showed red blood cells varying in number between 166 and 1,277 per ml. of urine. Hyaline and hyalogranular casts were found in 22%, varying between 0 and 14.7 per ml. of urine. In the subjects showing cylindruria, a determination of the glomerular filtrate by clearance of the endogenous creatinine showed normal values in all cases. The diet prescribed for the study of quantitative urinary sediment aimed at producing urine with a pH lower than 7 and a specific gravity of 1.024 or more—an important feature not only for the protection of the red blood cells but also for the evaluation of the facultative distal tubular capacity of urine concentration.

Antigen for Diagnosis of American Trypanosomiasis.—Dr. Victor Nussenzveig of São Paulo reported to the Associação Paulista de Medicina on a new antigen for the complement fixation test in American trypanosomiasis. The antigen described by Freitas and Almeida in 1949, now currently used for the diagnosis of American trypanosomiasis, is satisfactorily sensitive and specific, but its exact dose is difficult to determine for the quantitative technique, since it consists of a suspension of particles of varying dimensions. The author has made a new soluble antigen from Trypanosoma cruzi that possesses a good fixation power in mixtures with serums from diseased patients and that is not anticomplementary in the dilution to be used for the test.

ENGLAND

Public Health and Preventive Medicine.—The annual health congress of the Royal Sanitary Institute was held at Bournemouth in April. Prof. R. H. Parry of Bristol urged closer collaboration between the medical teaching centers and the public health departments so that medical students could learn more about conditions in the home, at school, and in the factory. A closer rapport between the general practitioner was needed so that he could assume medical responsibility at the health clinics and lessen the burden of the full-time health officers. Prof. Thomas McKeown of Birmingham said that, although prevention was better than cure, in National Health Service planning far too much effort had been put into curing established disease and insufficient effort put into its prevention. The improved health of today compared with that of previous generations is due primarily to the fact that much illness is preventable, rather than to improved methods of treatment. Dr. J. Brotherston of the London School of Hygiene and Tropical Medicine considered that the biggest problem facing the health service today was the care of the elderly sick. Efficient diagnosis and treatment are necessary to ease the strain on hospital beds and the country's finances, and prevention is important because it permits the aged to retain their independence. The hospital outpatient department must play an increasing part in the treatment of the elderly to relieve the pressure on hospital beds. The general practitioner must always bear the main burden of looking after old persons in their homes, where they should be able to get the benefit of ancillary services. There is no reason why the services of the physiotherapist, dietitian, social worker, and specialist should not be available in the home.

In the symposium on noise at work Air Vice-Marshal E. D. Dickson said that, in occupations associated with continual exposure to loud noise, impairment of hearing would result but, as in the early stages the impairment was in the appreciation of the higher frequencies, it was not always obvious. Intense noise injures the organ of Corti, the primary lesion being the destruction of the outer hair cells. A sudden loud sound may cause immediate destruction, but a continuous noise may cause a gradual change. Acoustic trauma occurs when the intensity of the noise is above 90 db. Auditory acuity should be determined before employment, so that compensation claims for impairment of hearing resulting from occupation can be properly evaluated. Furthermore some degree of deafness must be expected with advancing years. Proper planning and layout in factories helps to prevent excessive noise. T. S. Littler said that, although ear plugs reduce the appreciation of noise, there is a limit to the extent to which they do this, because sound vibrations are transmitted through the cartilage of the meatus and the bones of the skull to the ear. D. E. Broadbent of the Applied Psychology Unit, Cambridge, said that there was no evidence that excessive noise produced any impairment in mental health or behavior. Noise does, however, cause brief shifts of attention from the work in hand.

Aspirin and Peptic Ulcer.—Muir and Cossar have investigated the harmful effects of aspirin on the stomach, particularly in patients with peptic ulcer (*Brit. M. J.* 2:7, 1955). They administered 0.6 gm. of aspirin to 20 patients with radiologically confirmed peptic ulcers, after aspiration of the fasting gastric juice during a fractional test meal. The aspirin increased gastric acidity, and, in six of the patients, the specimens of gastric juice were blood-stained. The blood found in the aspirin test meals was in the form of blood-stained mucus and clots of altered blood, in contrast to blood of traumatic origin, which is fresh and bright red. A further point of interest was the conversion by aspirin of a previously consistently negative test for fecal occult blood to a strongly positive one in three patients. To study the effect of aspirin on the stomach, two uncrushed 0.3 gm. commercial aspirin tablets were given with a little water to 20 patients with peptic ulcer two hours before gastrectomy; another 20 had hard aspirin tablets; and another 20 had soluble calcium aspirin. Examination of the stomachs after removal showed the presence of macroscopic mucosal irritation in 12 of the 20 stomachs of patients treated with commercial aspirin. In three the irritation was severe. Microscopically the findings were typical of acute erosive gastritis. Of the 20 patients who received hard aspirin tablets, 8 showed typical acute erosive gastritis, 5 of them moderately severe. In only 2 of the 20 patients receiving soluble calcium aspirin was there any sign of mucosal irritation, and in these it was mild. The erosions were obviously the result of the local irritant action of the aspirin, since they often took the shape of the aspirin granule and remained in situ. In some cases the aspirin tablet was found embedded in the gastric mucosa.

About 300 people, representing an average cross section of the community, were questioned on their intolerance to aspirin. About 1 in 20 said that it gave them pyrosis, nausea, and, occasionally, epigastric discomfort. A series of 318 patients with peptic ulcer were questioned on their intolerance to aspirin; 25% associated a recurrence of symptoms with the taking of aspirin. In seven years 15 patients with severe dyspepsia were seen who were habitual aspirin takers and who were cured of their dyspepsia by its withdrawal. A most surprising result of the investigation was the fact that 33% of the patients admitted taking aspirin a few hours before a hematemesis. The authors state that there is also an "aspirin hematemesis" that occurs without a previous history of dyspepsia. They believe that, in patients with peptic ulcer who take aspirin, hematemesis results from an acute erosive gastritis induced by the drug. There was no evidence of defective blood coagulation or changed prothrombin time, thus excluding a salicylate-induced hemorrhagic diathesis as a cause of gastric bleeding. The authors recommend that aspirin should never be given to patients with peptic ulcer or dyspepsia.

Poliomyelitis and Tonsillectomy.—In 1951 the Medical Research Council appointed a committee to investigate the association between poliomyelitis and tonsillectomy, and its findings were published in *Lancet* (2:5, 1955). Since 1951 all health officers in England and Wales have submitted to the committee a routine report on each person in their areas said to be suffering from poliomyelitis. The reports showed whether the patients had undergone tonsillectomy within 12 months before the onset of symptoms. Patients reported to have had their tonsils removed within three months before the onset of poliomyelitis were selected for special investigation. A medical investigator visited the patients, the health officer, and the physician in charge of each case, and he then made a detailed record. A total of 114 such patients was reported on over a period of three years, and complete reports were obtained of 103 children up to 18 years of age who developed poliomyelitis within 91 days of tonsillectomy; 59% had symptoms 1 to 21 days after tonsillectomy. In the bulbar and bulbospinal groups the infection occurred 1 to 21 days after operation in 79% as compared with 38% of those in the spinal group and 31% in the nonparalytic group. Most of the cases occurred in the principal epidemic period, but a similar pattern was seen in nonepidemic periods. The committee concluded that tonsillectomy as practiced today adds only a few cases to the total number; however, although small as a community problem, for the patient who has undergone tonsillectomy it is important. The practice of restricting tonsillectomy in late summer, early autumn, or when poliomyelitis is rampant may diminish the number of postoperative cases; however, even if tonsils are removed only in the first six months of the year, the risk of developing bulbar poliomyelitis soon after the operation is still present. Records were also obtained of patients with a history of tonsillectomy at any time before the onset of paralytic poliomyelitis, and histories were obtained for matched controls. In a 5 to 15 year series of 203 patients, 35% had undergone tonsillectomy as compared with 22% of the controls. Percentage differences between patients and the controls were greatest in the group with bulbar paralysis, intermediate in the group with bulbospinal paralysis, and least in the group with spinal paralysis. The results indicated that persons who had had a tonsillectomy were more likely to develop the bulbar form of poliomyelitis than those who had not, even if years had elapsed between the removal of the tonsils and the onset of poliomyelitis.

Medicine and the General Election.—A general election was held on May 26. Both the Conservative and Labour (socialist) parties stressed health measures in their electioneering. The Conservative claim states that new hospital building was completely neglected by the last socialist government. Plans are now being made by the Conservative government to build new hospitals and to extend and modernize many existing ones. Worn out and obsolete equipment will be replaced and new beds provided. Stress will be placed on preventive medicine. "These are our priorities," say the Conservatives, "We rank them higher than free wigs or free aspirins." The party will encourage private practice and contributory health schemes, outside the health service, and will provide beds for paying patients in hospitals. The socialists oppose this. The Conservative party will also consider the problem of the aged and suggest schemes for their assistance when sick or infirm. It says that it is anxious to provide the best National Health Service the nation can afford. It has set up the Guillebaud Committee to study the problems involved. The party will make sure that adequate funds are available for medical research. It will do all in its power to further a national "clean air" policy.

The Labour party, if elected, will abolish all charges within the health service, including those for prescriptions, artificial teeth, and spectacles. It will also abolish all private pay beds in hospitals (but fails to mention that Labour politicians pay for medical treatment abroad by Continental specialists). Social security is to be carried a stage further with the institution of a Ministry of Social Welfare. The Labour party also promises to enforce clean food standards in shops and restaurants and to bring water supplies under public ownership.

Leukemia and Irradiation.—Brown and Abbatt have investigated the death rate from leukemia among patients with ankylosing spondylitis treated with roentgen rays (*Lancet* 1:1283, 1955). Preliminary data have been collected on 9,364 patients treated in 37 centers from 1940 to 1954. The expected number of deaths from leukemia in the series was calculated on the basis of the known death rates from leukemia in England and Wales for 1953. The observed deaths from leukemia among patients with ankylosing spondylitis were found to be at least 5 times and possibly as many as 10 times the expected number of such deaths. Among those patients given more than one course of irradiation the observed deaths were at least nine times those expected to occur from the ordinary mortality statistics. One explanation is that patients with ankylosing spondylitis may be unusually susceptible to the development of leukemia, but, in reviewing the findings in the light of reports in the medical literature and in the increased rate among patients who have had several exposures, it would seem that leukemia in most of these patients is associated with irradiation. An increase has occurred in the death rates from leukemia in both Nagasaki and Hiroshima, attributable to the atomic explosions over those cities in 1945. Other explanations for the high incidence of leukemia in these patients are, however, possible, and further investigations are necessary to confirm the findings. In the meantime, the authors consider that it would be wrong to withhold irradiation from those suffering from ankylosing spondylitis. What is certain, however, is that no one should be treated by irradiation until the diagnosis is clearly established and that a second course should not be given unless absolutely necessary.

Beryllium Poisoning.—A 22-year-old woman sued the Mullard Research Laboratories claiming that through their neglect she contracted beryllosis. This was the first action of its kind brought in the English courts. From July to September, 1947, she worked on an experimental process for producing fluorescent lighting tubes, which involved working with beryllium oxide and zinc beryllium silicate. She left in October, 1947, in good health but a year later was found to be suffering from chronic beryllosis, as a result of which, it was claimed, she would be a permanent invalid. It was held that her employers knew, or should have known, that beryllium was highly toxic. In defense the employers claimed that at the time they did not know the toxic hazards associated with the handling of beryllium compounds. The judge dismissed the plaintiff's claim stating that he was not satisfied that the employers should have known the process was dangerous at the time. The plaintiff appealed, but the Court of Appeal dismissed the case, one of the lords of the Court of Appeal dissenting. Lord Justice Denning said that the company concerned had decided to make their own fluorescent beryllium powders. If they had searched the literature they would have found articles in their own library (*American Chemical Abstracts*, Nov., 1946, and the *British Medical Journal*, Oct., 1943) stating that beryllium compounds were dangerous. They should have asked their medical officer to study the problem. He would have reported, as he did in giving evidence, that he knew that beryllium was toxic; however, the employers did not discover its dangerous nature until after 1947. The other lords of the Court of Appeal held that information on the toxicology of the substance was meager until after 1947.

Salaries in Public Health.—It is four and a half years since the salaries of physicians in the public health service were raised. The Ministry of Health has resisted any increase since that date, although the arguments in favor of it have been overwhelming. For example, physicians in the National Health Service in general practice and in the hospital service had salary increases in 1952 and 1954. The Whitley Council Committee recently failed to agree on the amounts by which public health salaries should be increased. The matter was therefore referred to arbitration to the Industrial Court for a decision. The physicians urged the court to equate salaries with those paid to doctors in other branches of the health service. On the other hand, the public health authorities, while agreeing to a salary revision, considered that physicians should not be paid any more than professional persons of comparable status in local government employment. The Industrial Court has sided with the public health authorities. There has been some disappointment over the new salary scales, because physicians employed in the public health service have long believed that for highly trained professional people they were underpaid. The new salaries for health officers represent an increase of about 10%. The commencing salary for a health officer in the smallest population groups (75,000 persons) is now $4,550, rising to $5,124 a year, and in the largest population group (600,000 persons) it is $7,000, rising to $8,120 a year.

The Fear of Cancer and Smoking.—Dr. Pyke of the Radcliffe Infirmary, Oxford, has conducted a survey of the 217 physicians working in Oxford hospitals. He found that 47.4% smoked and 27.5% had never smoked. These figures are lower than those for the general population. The percent who had never smoked agrees closely with Doll and Hill's finding of 28.5% nonsmokers among male physicians aged 35 to 44. In the group of physicians questioned by Dr. Pyke, the number who smoke is gradually declining. Eight years ago it was 61%, now it is 47.4%. The main reason given for the decline in smoking by the physicians was the high cost of cigarettes and not the risk of cancer, although this may have been a deterrent to starting the habit. This is supported by the fact that the number of physicians giving up smoking since an association with bronchial carcinoma was discovered has not increased. Only 56.5% of the physicians were satisfied with the evidence linking carcinoma of the lung and smoking. The proportion of those who accepted the evidence of an association between smoking and carcinoma of the lung was so much higher—five times—among the nonsmokers than among the smokers, present and past, that personal prejudice may have played a part in forming these opinions. The pleasures of tobacco addiction may have persuaded some of the smokers to discount the evidence of its dangers.

Death During Electroconvulsive Treatment.—At an inquest on a patient who died during electroconvulsive treatment, the North Bedfordshire coroner made the statement: "I hope that I will not have to consider any case in the future in which there is therapy involving loss of consciousness and cessation of breathing, however short, on the part of the patient, where only one doctor is present to administer the therapy and look after the patient in an unconscious state." The patient had undergone a pulmonary operation and subsequently suffered from acute melancholia. He was admitted to hospital, where he was given modified electroconvulsive therapy by a resident aided by nurses. The psychiatrist at the hospital, who had originated the form of therapy used, said that 4,000 to 5,000 treatments were given each year at the hospital without any mishap and that it would be impossible to have a trained anesthetist present whenever such treatment was given. The coroner suggested that in a case like this, where the patient had had a pulmonary operation, a second physician should have been present to give controlled respiration. He concluded that the patient had died from spontaneous pneumothorax and chronic pulmonary tuberculosis by misadventure after electroconvulsive therapy.

Death from Chloramphenicol.—Death following the administration of chloramphenicol was the subject of an inquest at Hammersmith, London. A 5-year-old girl had bronchitis in April, 1954, and the family physician prescribed "a teaspoonful of chloramphenicol three times a day." This presumably referred to an elixir of chloramphenicol palmitate, which was given to the child for three days. The bronchitis cleared up rapidly. On Nov. 24 the child was again brought to the physician with a rash on her face and legs and enlarged tonsils. At the time the symptoms were not associated with the administration of chloramphenicol. Later a blood cell count was taken, and on Dec. 1 the child was admitted to the Victoria Hospital for Children, Chelsea, with a diagnosis of aplastic anemia. Blood transfusions were given for several months but the child died on March 3, 1955. An autopsy confirmed the diagnosis of aplastic anemia. The pathologist thought that the condition resulted from the administration of chloramphenicol. It was, however, a rare complication, and he did not think that a physician could forecast the condition. Blood cell counts were not practicable for every patient taking chloramphenicol, and aplastic anemia often came on suddenly. The coroner recorded a verdict of death from misadventure.

Acetazolamide for Glaucoma.—The 75th congress of the Ophthalmological Society of the United Kingdom held in London in April included a symposium on acetazolamide. This has been used as an inhibitor of carbonic anhydrase, and because of its diuretic effect it has been used in the treatment of congestive heart failure. E. S. Perkins described the use of the drug at Moorfields Eye Hospital, where 58 patients with glaucoma had been treated with it. In about half the cases, which included congestive glaucoma, simple glaucoma, and glaucoma secondary to iritis and trauma, the intraocular tension was well controlled. In half of the remainder it was partially controlled or reduced for part of the time. The effect of the drug was increased by miotics. The dosage used was 500 mg. initially, followed by 250 mg. every six hours, and reduced after a few days to two or three times a day. The side-effects were diuresis and paresthesia. Acetazolamide was of particular value in the control of acute congestive glaucomatous crises, in simple glaucoma that failed to respond to miotics, and in iritic glaucoma in which intraocular tension could not be controlled until the underlying iritis had been allayed.

Fall from a Litter.—Just before midnight on March 17, 1953, an 86-year-old woman was admitted to a hospital for observation. She was placed on a wheeled litter, 2 ft. wide and 2 ft. 6 in. high, which had no guard rails, and wheeled into a cubicle. She was left unattended and fell off the litter, breaking her thigh. She sued the hospital for damages, alleging negligence. The evidence was that the patient had been left for five minutes, although her physician admitted that he was still in the room. The attending nurse said that the patient's condition was such that she did not require constant attention and that she had left the patient for 30 seconds to answer the telephone. Lord Uvedale testified that in his hospital there was one attendant per litter, night and day, and that in his opinion it was unwise and a mistake to leave a patient alone on a litter. After the fall the patient was in the hospital for nine months and had to have a pin inserted in her femur. The judge said that it was the duty of the hospital staff to take all reasonable care. The jury found for the plaintiff, awarded damages of $280, and added that someone should attend at all times a patient on a litter, if the litter has no guard rails.

PAINLESS MYOCARDIAL INFARCTION IN PSYCHOTIC PATIENTS

To the Editor:—Medical teaching stresses the central role of pain in the symptom complex preceding myocardial infarction. Dr. H. Zobel, psychiatrist in charge of the chronic service at this hospital, states that all psychiatrists have observed patients suffering from an acute surgical abdomen, ruptured gastric ulcer with peritonitis, gallbladder or renal colic, and coronary occlusion, with little or no subjective complaint of pain. This high pain threshold has been ascribed to many causes, none of them conclusive. The psychological mechanism is a complete withdrawal from reality and pain. Indian fakirs who are able to walk over red-hot coals with bare feet furnish an example of self-hypnosis rather than withdrawal. There is also the familiar case of the soldier so intensely excited during combat as to be oblivious of having been wounded until he sees his blood running or is unable to move further because of a shattered leg. Persons may be hypnotized into a trance and told they will not feel pain. On being awakened they submit to pin pricks without flinching and state that there is no pain sensation present. Hysterical anesthesia is likewise a familiar phenomenon. W. E. Marchand (*Bedford Research*, vol. 4, 1953; *New England J. Med.* 253:51, 1955) has collected a series of 99 psychotic patients in whom a diagnosis of myocardial infarction was made. In 83 the diagnosis was confirmed by autopsy or electrocardiogram. Of these, 51 met criteria for being considered acute. Chest pain was present in only seven of these. If the 32 chronic cases are added only 7 of the 83 patients had pain as a presenting symptom. Marchand also observed that four patients had a diagnosis of acute infarction because of a change in their psychotic behavior. He compares the psychotic with a normal patient who had a lobotomy for relief of pain in that to such a patient meaning of pain is lost. At our hospital in the last two years, a new diagnosis of coronary thrombosis was made on 56 inpatients and seven nonpsychotic admissions. Of the latter only one died (after only 12 hours in hospital), and all seven had typical pain as the presenting symptom. Of the 56 inpatients the diagnosis was confirmed at autopsy in 21 and by unequivocal electrocardiographic tracings in the rest. Only seven of these noted any pain, and only three had pain as the presenting symptom. Thirty-one deaths in 56 patients gives a mortality of 55%. The usual expected hospital death rate is about 25%. As our hospital population averages about 2,500, this made us suspect there were in the wards 30 to 50 patients with relatively recent infarctions that had given no symptoms and were, therefore, unsuspected. We have started an intensive electrocardiographic survey of all patients over 35 years of age. We have already indications that the final number of cases so picked up will be higher than the expected projection curve.

In July, 1953, and August, 1954, one 57-year-old patient had a normal electrocardiogram, although benign hypertension was present. He was markedly delusional but cooperative. On Feb. 25, 1955, he was seen by the psychiatrist because an aide observed him to be "extremely quiet." At that time his blood pressure was 155/85 mm. Hg, and he had no complaints of any sort. He was satisfied to work in the clothing room. An electrocardiogram revealed evidence of a massive, anterolateral infarct. The patient made an uneventful recovery. On March 3 his leukocyte count was 13,600 per cubic millimeter and his sedimentation rate was 75. His rectal temperature never exceeded 100.6 F. A 63-year-old patient, while in the dining room, was observed by an aide to become pale and stop eating. He was transferred to the medical ward. The first electrocardiogram was normal. His physical examination was completely unrevealing. He was nevertheless kept for observation, and two days later an electrocardiogram revealed evidences of a massive anterior infarct that proceeded to go through the usual evolutionary pattern. Throughout the course of this attack the patient was comfortable and had no complaints. The most important observation to be made from the above is our complete agreement with Marchand's conclusion that we have to depend on the alertness of psychiatric aides who live with patients from day to day to call attention to any change whatever in the behavior of the patients in their charge. Psychotic patients simply do not verbalize what should be severe pain. It is not that they are inured to sensation but that their withdrawal prevents the pain from penetrating to their consciousness. It is of the greatest practical importance for all physicians to recognize this phenomenon. In making a diagnosis when examining a known or even suspected psychotic this absence of pain must be taken into account. Whenever the condition objectively points to a coronary occlusion, ruptured peptic ulcer, biliary or renal colic, or any other usually painful disease, the lack of pain must not deter one from making the proper diagnosis and instituting appropriate therapy. Many organic ailments of psychotic patients go untreated because they are undiagnosed.

Veterans Administration Hospital
Northport, N. Y.

STUDYING THE PATIENT

To the Editor:—As a psychiatrist and psychoanalyst who presumably would be classified as an "orthodox Freudian," I would like to make a few comments on Dr. John D. Campbell's article "Manic Depressive Disease in Children" in The Journal, May 21, 1955, page 154. In his concluding paragraph, he states that patients should be studied as if the physician were the original observer, and warns against stereotyped formulations. I heartily concur with these sentiments and feel this attitude should always prevail. However, in the description of etiological factors attributed to the so-called psychodynamic school, he calls attention only to environmental factors such as parents, cultural and social setting, and trauma. These can be very important undoubtedly. Yet, if this were all the "psychodynamic school" had to say, I would join Dr. Campbell in his criticism and underline his statement to consider the possibility of illness within the child himself. Dr. Campbell fails to mention the very group of factors that psychoanalysts have stressed as basic in the cause of psychological illness. For brevity we can refer to this group as initiating in the instinctual drives and subsequently developing psychic conflicts. According to psychoanalytical theory these basic drives are biological and form the substrata for mental life. They are the motivating force for healthy development as well as mental suffering. No treatment is adequate that fails to acknowledge their etiological role. To think of neurotic disease and affectual disorders as predominantly due to environmental factors is a serious distortion of basic psychoanalytical principles. Freud's work focussed initially on precipitating factors in neuroses of adults, and his early formulations suggested traumatic factors in childhood (e. g., seductions). In 1897 he wrote to W. Fliess that his theory was wrong (*The Origins of Psychoanalysis: Letters to Wilhelm Fliess, Drafts and Notes: 1887-1902*, edited by Marie Bonaparte and others, translated by Eric Mosbacher and James Strachey, New York, Basic Books, Inc., 1954, letter 69, p. 215). In a paper "Sexuality in the Neuroses," written in 1905 (Collected Papers, London, Hogarth Press, Ltd., 1948, vol. 1, pp. 276-277) he corrects the traumatic theory, calling it erroneous in the majority of cases. In his Introductory Lectures of 1915-1917 (A General Introduction to Psychoanalysis, translated by Joan Riviere, Garden City, N. Y., Garden City Publishing Company, Inc., 1943, p. 322) he states that such recollections need be only psychically real (i. e., real in the person's mind) to be of significance in the developing conflict, as the unconscious does not differentiate psychic reality from outer reality. The pendulum often tends to overswing. The "psychodynamic principles" of Freudian analysis appear to have been greeted with great enthusiasm by the public. Yet it was a cause of great concern at the International Psychoanalytical Congress of 1951, in Amsterdam, Netherlands, that the present-day understanding of such principles appeared to be creating a generation of guilty parents rather than a healthy mental life for children and parents. This could be due to a misconception similar to the one Dr. Campbell's article suggested. We do not belittle constitutional factors. They are the basis for mental functioning. It is through the study of how the person has coped with his instinctual drives that therapy proceeds. In the process, better solutions are often found and outmoded methods discarded. Simultaneously psychoanalysis learns more about the nature of endopsychic conflicts.

GOVERNMENT SERVICES

NAVY

Medical Reserve Courses.—A six day seminar for commanding officers of Naval Reserve medical companies will convene in the bureau of medicine and surgery, Navy Department, Washington, D. C., on Oct. 31. All naval districts have been assigned a quota for this seminar. A 14 day course of on-the-job training in submarine medicine will be conducted by the Naval Medical Research Laboratory, Submarine Base, New London, Conn., commencing on the first Monday in August and November, 1955, and February and May, 1956. Quotas for reserve officers of the Medical Corps and Medical Service Corps only have been assigned to the first, third, fourth, fifth, sixth, eighth, and ninth naval districts. A 14 day course of on-the-job training in medical research is offered at the Aviation Medical Acceleration Laboratory, Naval Air Development Center, Johnsville, Pa., July 4-17, July 18-31, Aug. 1-14, Aug. 15-28, and Aug. 29 to Sept. 11, 1955. Quotas have been assigned to the first, third, fourth, fifth, and ninth naval districts. Medical ensigns (1995) who have successfully completed the first year of medical school and who are interested in medical research and development are eligible for this training. A five day course in special weapons, isotopes, and military medicine will be given at the Naval Station, Treasure Island, Calif., starting Feb. 27, 1956. Quotas have been assigned to the 11th, 12th, and 13th naval districts. For further information on these and other training opportunities send inquiries to the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

New Rear Admirals.—The President, on Aug. 1, 1955, approved the report of the Selection Board, which recommended the following named medical officers for temporary promotion to the grade of rear admiral in the Medical Corps: Capt. Courtney G. Clegg, commanding officer, U. S. Naval Hospital, Philadelphia; Capt. Hubert J. Van Peenen, staff medical officer; and Capt. Thomas G. Hays, commanding officer, U. S. Naval Hospital, Mare Island, Calif.

Personal.—The following officers of the medical department have been placed on the retired list effective July 1: Rear Adm. Clifford A. Swanson and Capt. Hugo O. G. Wagner on the temporary disability retired list; Rear Adm. Eugene R. Hering Jr., Capt. Lewis T. Dorgan, Capt. Thomas Q. Harbour, and Capt. Charles W. Shilling on the retired list.——Dr. Howard T. Karsner, research advisor to the surgeon general, has been appointed as the general consultant of the medical advisory board of the Leonard Wood Memorial (American Leprosy Foundation).——Lieut. John G. Gordon, M. C., U. S. N. R., now on duty under instruction at the Naval School of Aviation Medicine, Pensacola, Fla., will become the Navy's first "resident" in aviation medicine at the school upon completion of the basic course in aviation medicine in September.

PUBLIC HEALTH SERVICE

Committee Appointed to Review Research Programs.—A special committee on medical research has been named by the National Science Board to review and evaluate the medical research programs of the Department of Health, Education, and Welfare, at whose request the review is being made. The committee is headed by Dr. C. N. H. Long, chairman, department of physiology, Yale University School of Medicine. Other members are: Dr. E. A. Doisy, professor of biochemistry, St. Louis University School of Medicine; Dr. Ernest W. Goodpasture, Armed Forces Institute of Pathology, Walter Reed Army Medical Center; Dr. A. B. Hastings, department of biological chemistry, Harvard Medical School; Dr. Charles Huggins, director, the Ben May Laboratory for Cancer Research, University of Chicago; Dr. Colin M. MacLeod, department of microbiology, New York University School of Medicine; Dr. C. Phillip Miller, department of medicine, University of Chicago; and Dr. W. M. Stanley, director, virus laboratory, University of California. Dr. Joseph W. Pisani, assistant dean, State University College of Medicine at New York City, is serving as executive secretary of the committee.

In the department's request to the foundation the secretary requested that review of the department's program include the following: consideration of the rate of growth of the programs of the National Institutes of Health, other research units of the Public Health Service, and other units of the department, in the light of the responsibilities of the federal government with respect to health, medical, and related research; general appraisal of the present level of support of medical research by the department; careful consideration of the proper balance of effort with respect to the support of basic research and research aimed more directly at the prevention, diagnosis, care, and cure of diseases; and appraisal of the relative distribution of effort among the major special fields of health research.

Regular Corps Examinations for Medical Officers.—A competitive examination for appointment of medical officers to the regular corps of the U. S. Public Health Service will be held in various places throughout the country on Nov. 15-17, 1955. Appointments provide opportunities for career service in clinical medicine, research, and public health. They will be made in the ranks of assistant and senior assistant, equivalent to Navy ranks of lieutenant (j. g.) and lieutenant respectively. Entrance pay for an assistant surgeon with dependents is $6,017 per annum; for senior assistant surgeon with dependents, $6,918. Provisions are made for promotions at regular intervals. Benefits include periodic pay increases, 30 days of annual leave, sick leave, medical care, disability retirement pay, retirement pay, which is three-fourths of annual basic pay at time of retirement, and other privileges.

Active duty as a Public Health Service officer fulfills the obligation of Selective Service. Requirements for both ranks are U. S. citizenship, age of at least 21 years, and graduation from a recognized school of medicine. For the rank of assistant surgeon, at least 7 years of collegiate and professional training and appropriate experience are needed, and, for senior assistant surgeon, at least 10 years of collegiate and professional training and appropriate experience are needed. Entrance examinations will include an oral interview, physical examination, and comprehensive objective examinations in the professional field. Application forms may be obtained from the Chief, Division of Personnel, Public Health Service, Washington 25, D. C. Completed application forms must be received in the Division of Personnel no later than Oct. 15, 1955.

Course on Serology of Syphilis.—Nine laboratory refresher courses on the serology of syphilis and tests for syphilis using the Treponema pallidum will be offered at the Venereal Disease Research Laboratory in Chamblee, Ga., from September, 1955, through May, 1956, the Public Health Service's venereal disease program announces. The schedule of courses is as follows:

Sept. 26-Oct. 7, 1955, Serology of Syphilis.
Oct. 24-Nov. 4, 1955, Serology of Syphilis.
Oct. 31-Nov. 10, 1955, Tests for Syphilis Using the Treponema Pallidum.
Jan. 9-20, 1956, Serology of Syphilis.
Feb. 6-17, 1956, Serology of Syphilis.
March 12-23, 1956, Serology of Syphilis.
April 2-13, 1956, Serology of Syphilis.
April 16-27, 1956, Tests for Syphilis Using the Treponema Pallidum.
April 30-May 11, 1956, Management and Control of Syphilis Serology by the Regional Laboratory.

The Serology of Syphilis courses are designed to provide refresher training to senior operating personnel of state and Public Health Service laboratories. Applications must be signed by the state health officer or state laboratory director unless the applicant is an employee of the Public Health Service. In such instances application must be approved by the medical officer in charge. Application blanks may be obtained from the address below. Correspondence about these courses should be addressed to: Director, Venereal Disease Research Laboratory, Division of Special Health Services, Public Health Service, P. O. Box 185, Chamblee, Ga.

BUREAU OF MEDICAL ECONOMIC RESEARCH

THE MAGNUM OPUS OF MICHAEL DAVIS

Frank G. Dickinson, Ph.D.

Michael Davis' most recent book, "Medical Care for Tomorrow" (New York, Harper & Brothers, 1955), is a well-organized compilation of the efforts of a lifetime to persuade the American people to accept socialized medicine. His earlier writings on this subject have been voluminous, and this book definitely establishes Michael M. Davis as the most diligent and, from many points of view, the ablest advocate of the socialization of the practice of medicine. A full-scale review covering every chapter would be another volume. We shall merely try to present the flavor of this book.

The approach taken in the volume is set forth in the preface (ix): "I am of course aware that a number of physicians are not accustomed to economic and social analysis. . . ." As early as page 18 one wonders if Davis is competent to present an economic and social analysis for physicians or anyone else. He gives as the "rates of increase," 1929-1950, drawn from Department of Commerce consumer expenditure reports: medical care, 2.75 times; tobacco, 2.6 times. The correct increases were only 1.82 and 1.60—that is, increases of 182% and 160%. Apparently he does not know the difference between a ratio, an increase, and a rate of increase. In the text he refers to the period 1929 to 1950 but states in the footnote the "rate of increase" for alcoholic beverages was for the period 1940-1950. Had he chosen 1930-1950 instead of 1929-1950 he would have reported that the increase for tobacco was 204% and the increase for medical care was only 192%—the ratios were 3.04 and 2.92.

"BUNDLES OF JOY"

But let us be as fair as possible to this sociologist who is not familiar with customary economic and statistical terms and choose a period of time for him during which data on personal consumer expenditures for alcoholic beverages along with his other items are available—most readers know that the sale of alcoholic beverages was not reported by the Department of Commerce in 1929, the boom year of the prohibition era. The 1953 personal consumer expenditures exceeded those of 1945 by the following percentages: medical care, 98; tobacco, 79; recreation, 94; jewelry, 26; personal care, 33; and alcoholic beverages, 18. We chose this post-World War II period knowing that it would show a higher percentage of increase for medical care than for these other items for the purpose of *illustrating* a fundamental defect of the book and of Davis' point of view. Why did personal consumer expenditures for medical care increase more during this eight year span than for the other selected items? Was it because this was an extremely unhealthy period? Was it because the American people were being robbed by their physicians? Does it manifest the failure of fee-for-service? Does it result from the slowness of development of restrictionist group-practice schemes? Would the percentage increase for medical care have been much less under national health insurance? Was it because hospital room rates and physicians' fees were rising too rapidly? The major reason for the more rapid increase of medical care expenditures was an extra million and a quarter "bundles of joy," for the birth rate rose by leaps and bounds during this eight year period; and births increasingly involve hospital expenses for the family.

Davis does not divide the people into tall and short, old and young, but simply into two ironclad groups—the sick and the well. He tries to give the impression that all expenditures for medical care are for disease or trauma, but he never separates them. The fact that some medical care expenditures are for childbearing did not fit into his propaganda scheme. We doubt that he would attempt to prove that pregnancy is a disease. How well people spend their money other than for health insurance is no problem for Davis. How the sick people spend money for things other than medical care is not his concern. A person is either sick or well. One cannot help but admire the courage of Davis in thinking he could prepare a comprehensive analysis of medical care for physicians or anyone else without recognizing that there are many ways of classifying the American people. He is careful, however, to avoid saying specifically that every cent spent for medical care is an expenditure for a necessity, but the whole tenor of the book plays down the opportunity for free choice in a free society.

ORGANIZATION OF BOOK

The most simple statement that might be made to characterize the organization of this book would be that it breaks down the medical care complex into three elements: the personal, the organizational, and the economic. The first three of the four major parts of the book are devoted to definition and historical survey of each of these segments, with indication by the author of what he considers to be the problem areas involved. On basis of this dual objective-subjective approach, he projects his opinion of the direction of change and the tack that should be taken by society. In the final part of the book he summarizes his analysis and presents what may be defined as a general outline for social planning for the medical care field in the future.

The six chapters of part 1, Basic Elements in Medical Services, are an analysis of what he considers to be the fundamentals of medical service: people; their health needs and demands; physicians and allied professions; and the economics, organization, and quality of service. Davis' approach is to analyze the problems within each area; for example, the inherent difficulty the consumer faces in trying to assess quality of medical care; and conflicts within the profession itself, as between salaried physicians and self-employed practitioners. It is in this section that he develops his principal thesis: that science and technology have so transformed medicine that revolutionary changes in the entire realm of medical care are both necessary and inevitable.

Part 2, Evolution in Organizations, comprising chapters 8-14, deals with the historical development of organizations and public services having to do with the field of medicine. Included is a chapter (12) dealing with what Davis considers to be the dilemma of the physician, torn between professional and financial incentives under a fee-for-service system. He also deals with the nature and realm of tax-supported medical care. A major part of the writing is an attack on the organized medical profession. This criticism is then linked to his analysis of what he considers to be the changed relationship between physicians and hospitals. Briefly, it is his contention (as it has been for several decades) that the trend toward larger, general hospitals engendered by scientific and technological developments has been of such magnitude that medicine is no longer conducted by individual physicians; the hospital is and should be the unit around which medical care is organized.

Part 3 is entitled Evolution in Economics, chapters 15-18. Davis traces the growth of health insurance and deals with the controversy of proprietary (voluntary) versus social insurance. This discussion aims at establishing three points: (1) comprehensive insurance is possible; (2) the indemnity approach is limiting; and (3) the voluntary principal has, by definition, certain basic disadvantages. He also traces legislation and politics as they pertain to medical care. In effect, this is an attack on the methods and purposes of organized medicine in opposing certain federal health legislative proposals. Part 4, Programs and Outlook, chapters 19-27, is given over to methods of implementing the policies that Davis has outlined as desirable

---

Director, Bureau of Medical Economic Research.

in preceding sections: replacement of fee-for-service payment; encouragement of group practice, particularly when linked with an exclusive prepayment plan; and gradual progression toward comprehensive national health insurance. Davis sums up his book as follows: "The analysis of past and present forces made in this book justifies the conclusions, that this demand [for comprehensive coverage] is already sufficiently widespread to be a politically significant force irrespective of political party; that the demand will continue; and that it will bring almost universal group payment, as it gradually focuses upon specific objectives" (page 371). There are four appendixes, the last of which is a long bibliography that, because of omissions, will be of greatest use to his followers.

The final chapter, From Today into Tomorrow, stresses "gradualism," which he would expedite so that we might have the full benefit of government control of medicine as soon as possible. In many ways this last chapter is the most mellow of all of Davis' writings. The objective is still clear, national compulsory health insurance, but we must not try to attain the goal with too much haste; however, the goal is inevitable. It will be attained no matter what physicians or nonsocialists may try to do about it; it is only a question of time. So the dominant note of this book is that socialized medicine is inevitable and we must accept it.

IS SOCIALIZED MEDICINE INEVITABLE?

The trend toward socialism in the United States is beyond dispute. Big government is playing an increasing role in our lives, in the field of medical care as in almost every other aspect of our lives. The fact that the government role has increased is not news. Davis, of course, does not discuss the increasing role of government in the lives of well people but only the increasing role of government in medical care. Whether this aspect of increasing government control is lagging or leading is of no concern to him; it should be to a writer concerned with medical care today and tomorrow, for it is the relative increase in government control that is significant in forecasting.

One of Davis' principal criticisms of the American medical profession today is its fee-for-service system of payment. This system, under which the indigent are treated for low fees or no fees and the high income groups are charged higher fees, is inadequate, according to Davis, because: (1) it is difficult for the physician to measure ability to pay, and (2) the range in cost of procedures has increased so greatly. Davis advocates a method of fee determination similar to collective bargaining between groups of physicians and consumers. Eventually, he points out, fee-for-service payment will be impossible; under any sort of broad medical care plan standardized fees would be imperative. In other words, only through government could the "proper" charges be made for the services of physicians.

There are many who will not heed this voice of impending doom to the fee-for-service system. There are many who believe that there is an ebb and flow in the role of government in the history of mankind, and the present may merely be one of the high peaks in that undulating wave. Even if government control of medicine is "inevitable," they will want to postpone the evil day as long as possible, for all that is inevitable is not good. Davis' buildup of this bugaboo of inevitable government absorption of the medical profession by careless use of statistics is of only minor importance. For example, he worries a good deal about whether the expenditures of the Department of Defense should be added to personal consumer expenditures for medical care, but he does not even mention the medical expense of the Veterans Administration for the care of veterans with service-connected disabilities. It seems to us that both of these public expenditures are clearly costs of present, past, and future wars and are not to be confused with the expenditures people make as consumers for medical care. Davis is correct in pointing out that the role of government in the medical care of the American people has increased during recent decades. This note of inevitability is a familiar device that has been used frequently—perhaps most effectively by Karl Marx in predicting the ultimate domination of the bourgeois by the proletariat in his two-class approach to social evolution.

We have noted Davis' lack of consideration of the medical cost of childbearing as a rapidly expanding type of medical care expenditure. Under the prevailing fee-for-service system, which he considers anachronistic, it is possible today for a husband to tell his wife that her chances of dying in childbirth are only one-ninth of the chance that her own mother had of dying in childbearing a generation ago. Surely the phenomenal reduction in the risks of childbearing has been a factor in the rapid increase in births and the accompanying medical expenditures. Presumably Davis would answer this comment by merely saying that there are still more than 2,000 maternal deaths (pregnancy and childbirth) in the United States each year and this proves the need for replacing the fee-for-service system. Such a retort would be very difficult to answer, for it implies that the prevailing system of medical economics is a failure if anyone dies. Going to the other extreme of life, the death rate during the first decade of retirement, ages 65 to 74, has declined about 30% since 1900. The great accomplishment of the 20th century, which is that we are dying old instead of dying young, is not mentioned, because Davis has little interest in what we get for what we spend for medical care under our present fee-for-service system. There is, in fact, little reason why a man blinded by what seems clearly inevitable to him should be interested in such mundane questions of medical economics as demand and supply, price and value, and buyer and seller.

SOME FAMILIAR CLICHÉS

The book abounds with many of the clichés repeated over and over again by the advocates of socialized medicine. Let us examine a few of them briefly but critically. A consumer is not competent to select one physician and should only select a group—if more than one group is within reach. Admittedly, medical care is often an unwanted consumption item, but Davis does not seem to have any way of making the purchase of medical care as attractive as purchasing a new television set; unless, perhaps, compulsory purchase through the collection of "insurance" taxes—from some—might make the purchase of medical care seem painless. Room rates in hospitals have risen rapidly, but Davis does not warn the reader that under socialized medicine hospital room rates would probably have risen much faster. Certainly the example of per diem costs in Veterans Administration hospitals for veterans with non-service-connected disabilities does not indicate that socialized hospitals would reduce the cost per patient day. He also repeats the error of so many in his claim that the percentage of income spent for medical care is higher in the low income families without first classifying families by the age of the members. The fact that the maximum frequency of physician visits is to preschool children whose parents are in the low earning period of life gives rise to the illusion that low income families spend a higher percentage of their incomes for medical care; the percentages may well be about the same for families of a given age distribution with different incomes. He claims that the earnings of physicians as a group are higher than those of any other profession. The United States Department of Commerce in its surveys prior to World War II pointed out that the incomes of certified public accountants and consulting engineers were considerably above those of physicians. Although no comprehensive postwar study has been made of the incomes of these two professions, the income tax has not become less complicated and the building boom has certainly increased the demand for services of the consulting engineer. The simple fact is that the average income of physicians since 1929 has increased at almost exactly the same rate as the average incomes of all gainfully employed people, thus indicating an economic balance between supply and demand.

In one of his many references to publications of the Bureau of Medical Economic Research (page 55) he again reveals his inability to handle statistics. Specifically he charges that the claim of increase in "output per physician" since 1940 is questionable because all physicians do not have the same skill, facilities, and assistance; some have more than average and some have less than average, but the gain in output per physician was very marked. His charge (page 103) that the American Medical Association is not a democratic organization because the Trustees and not the House of Delegates approve budgets is wrong on two counts. First, we would remind Mr. Davis that in our federal system the members of Congress do not elect the members of the President's cabinet, but the A. M. A. House of Delegates does elect the Trustees. Second, the financial operations of the Association are carefully scrutinized by the House of Delegates.

In chapter 17, Proprietary Versus Social Insurance, and elsewhere in discussing the economic side of medicine Davis seems to be unaware of the large volume of personal savings. Certainly medical care is one of the rainy days for which people save, and these savings are often available for medical care expenditures, making the use of current income unnecessary. Voluntary insurance to prepay all manner of "five and dime" claims is not necessary, and the overhead costs of operating such a "complete" voluntary health insurance system would be a dead weight on the American consumer.

The socialist's distaste for small business is manifested time and time again in his approach to group practice, which is not increasing as rapidly as he thinks it should. He pointedly omits distinguishing between group practice per se—to which the A. M. A. has no objections—and group practice as an agency for delivering the medical care purchased through a prepayment plan that permits only the particular group of physicians to provide the medical care for which the prepayment was made. Several members of the Board of Trustees of the American Medical Association have spent most of their professional lives in medical groups.

It is on the subject of rural practice that the author reveals a complete lack of consistency. In one place he bemoans the shortage of physicians in rural areas (chapter 25) and elsewhere advocates concentrating physicians in group practices in well-located cities. This is equivalent to saying that we can have our cake and eat it too—that if there were 3 physicians in a large town and 10 more in each of 10 widely scattered small towns within a radius of 100 miles, the way to provide more physicians in rural areas would be to persuade these 10 physicians to leave the 10 small towns without a physician (or import them from elsewhere), join the 3 physicians in the largest town, and form an "efficient" group practice.

SUMMARY

In summary, this volume appears to be an encyclopedic treatment of problems in medical economics, but it is really a restatement of the views of a socialistic planner who wants to dispense with the private practice of medicine as soon as that inevitable day of grace can be accomplished. No miracle man, gazing at the promised land, is needed to solve the present and future difficult problems of the medical profession in its continuing efforts to improve the quality of medical care.

Carcinoma of the Larynx.—An average of 135 patients with this condition are seen annually at the Mayo Clinic. This is approximately 120 patients per 100,000 clinic registrants. Like malignant disease of the mouth and pharynx, it is encountered much more frequently in males than in females, the proportion being more than ten to one. . . . Carcinoma of the larynx can be cured in an appreciably higher percentage of cases than at present if these lesions are diagnosed in an earlier stage. Although patients with this condition are now consulting laryngologists more promptly than a decade or two ago, in a number of them the process is already well advanced at the time of the initial visit. Many of them require radical surgical treatment which might well be avoided, if the physician consulted primarily suspects the serious nature of the laryngeal lesion. Most of these neoplasms develop on the vocal cords, and a change in the quality of the voice, or persistent hoarseness, generally occurs early. Accordingly, keener appreciation of the possible significance of chronic hoarseness by the physician and the laity will improve the present situation. Continued education of the public, too, will help but it is essential also that the physician maintain a high degree of suspicion.—F. A. Figi, M.D., Carcinoma of the Larynx and Its Present-Day Management, *The Annals of Otology, Rhinology and Laryngology,* March, 1955.

PUBLIC RELATIONS

The material appearing in this column is prepared in the office of the Public Relations Department of the American Medical Association.—Ed.

TULSA HEALTH SURVEY

A health survey of the city of Tulsa, Okla., conducted by the Tulsa County Medical Society and the health division of the Tulsa Council of Social Agencies, has revealed a generally favorable attitude toward the medical profession, although some deficiencies and weaknesses were disclosed. Assisting in the study was a technical committee from the Tulsa chapter of the American Statistical Association, which adjudged the survey data to be "representative of the opinions and characteristics of the population." Some of the principal findings, most of which should have a public relations interest for physicians and medical societies, follow.

Eighty-three per cent of the people interviewed believe that there is a need for some system of assuring emergency medical care. Eighty-four per cent think that a physician should discuss his fees in advance with the patient. Over half—54%—consider Tulsa physicians' fees to be reasonable, but 30% think they are too high. The remainder have either no opinion or mixed opinions. Eighty-seven per cent have a regular physician either for adults, for children, or for both. Eighty-three per cent of the people who have had a family member hospitalized within the past year are satisfied with the services rendered at Tulsa hospitals. Sixty-one per cent of the people who have had a family member hospitalized within the past year consider hospital charges to be reasonable, but 32% think they are too high. Seventy-four per cent of the families have health insurance of some kind, either Blue Cross, commercial, or a combination of the two.

In the field of preventive health measures, the survey revealed that only 37% of Tulsans had had a physical examination during the previous year, and only 32% had had a chest x-ray in 1953. However, 74% had had a chest x-ray at some time in the past. Among children under the age of 6, only 21% had been vaccinated for smallpox, and 62% had received all three injections for diphtheria, whooping cough, and tetanus.

The questioning on the need for an emergency call plan revealed that, out of 485 families covered in the survey, 90 (or 19%) reported at least one medical emergency during the previous year. Of those 90 families, 9 said they had had difficulty in obtaining the services of a doctor. Of the 9 experiencing difficulties, 5 were among the 77 families having a regular physician and 4 were in the group of 13 families without a regular family doctor. The opinion favoring an emergency call system was by no means limited to those without regular physicians or to newcomers in the city; in fact, it was strongest among those with family doctors and among those living in Tulsa for three years or more. Of the 404 families favoring an emergency medical call plan, 86% had a regular doctor. Among the 414 families living in Tulsa for three years or more, over 84% favored an emergency plan.

The survey report made the following comment on this phase of the study: "In analyzing the comments made it was found that (1) many informants saw no need for an emergency medical call plan for themselves but recognized a potential value to newcomers and other persons without the services of a regular doctor, (2) the desire of the informants for such a plan was based in large measure upon a fear of being unable to obtain a doctor when needed. Thus the plan appears to be desired as an element of community security."

A question concerning Tulsans' preference as to the best location for their physician's office brought the following results: 46% preferred a residential area; 23% favored a downtown location, and 31% were equally agreeable to a downtown or residential office site. On the subject of advance discussion of fees by physicians, most of the informants stressed its value in budget planning, particularly when extensive surgery or prolonged medical care were indicated. Some were critical of physicians who in the past had failed to discuss fees or had put off the discussion with vague statements about costs. Analysis of the opinions on medical fees showed that the higher the income, the more favorable was the viewpoint toward physicians' charges. The major criticism of hospital services was the shortage of nurses.

Dr. John G. Matt headed the health survey steering committee, and Mr. Milton Searl was chairman of the technical committee. Miss Lois Tubb, secretary of the health division of the Tulsa Council of Social Agencies, served as secretary and coordinator for the project. The survey findings were put into manuscript form by Mr. Jack Spears, executive secretary of the Tulsa County Medical Society. Assistance in the tabulation and review of statistics was given by Mr. Lyndral Marcum and Mr. Frank Craig, both of the Blue Cross-Blue Shield Plans of Oklahoma.

MISCELLANY

ADDRESS BY NORMAN VINCENT PEALE, D.D.

When I began my ministry in 1923, I had no concept of any direct relationship between religion and medicine. One recognized, of course, that right living was an aid to well-being, but only in a general sense. Religion seemed primarily a system of ethics and theology concerned with man's relationship to God, with the moral and spiritual betterment of the individual, and the improvement of social conditions.

Medicine, we regarded as a scientific practice having to do with the cure of disease entirely through materialistic processes. I was a strict materialist as to medicine and regarded as cranks those who described case histories of healings in which faith was claimed as a factor. Caution still seems indicated in the acceptance of non-medical healing beyond the religio-psychosomatic influence. But that amazing phenomena *do occur* which are seemingly of God and outside the framework of man's knowledge, we would not deny.

Being of a somewhat scientific turn of mind, although not a scientist, I found it difficult at first to think of religion as more than comfort and solace in time of illness. But gradually, the realization that we live in a dynamic universe and the growing acknowledgment of a world of reality beyond the material affected my thinking, as no doubt it did yours.

Yet, it was the repetition of certain experiences that convinced me that as ministers we have a part in the healing work of God. I re-studied the Bible from this point of view, and was amazed to note the repetitive emphasis upon its principles as factors in the total well-being of man. One experience will illustrate.

A woman outlined a number of ways in which she felt ill physically, emphasizing her fears and tensions. I had a curious feeling as I listened to her unhappy recital that a grey veil was over her face. There was, of course, no such veil, but the impression might perhaps have been gained from an emanation of her unhappy spirit. I thought of it recently when an advertisement appeared in the paper picturing a harried and worn man, head in hands. Beneath the picture was a caption which read, "Have you that grey sickness—half asleep, half awake, half dead, half alive?" Physicians have told me that a long held mass of unhappy thoughts can produce physical symptoms of illness.

Indeed, when I asked this miserable woman her doctor's opinion, she quoted him as saying, "You are draining back into your body the diseased thoughts of your mind." This impressed me as a most expressive insight.

STORY OF FAITH

Then occurred an amazing happening. I asked her if she believed in the actual healing presence of Christ. She replied that she did. I then explained that worry may be described as a spasm of the emotions, in which the mind catches hold of a thought or obsession, clutches it spasmodically and will not let it go. To break its hold, one must gently, but forcibly, insinuate a healthier and stronger idea into the mind's convulsive grasp. This stronger idea that we desired her mind to take hold of was faith in the healing grace of Christ. So, I asked her to affirm aloud, "Jesus Christ is by my side. He is touching my mind, my body, my soul with His healing grace." Apparently her mind opened and received this truth, for there began a process of change that presently freed her from her fears and tensions and brought her to a state of well-being.

TRIBUTE TO PHYSICIANS

What little experience I have had in this field certainly does not qualify me to discuss so important a subject before so eminent an organization as the American Medical Association. But I appreciate the very great honor of addressing your distinguished body. Feeling my inadequacy, I have drawn upon such experts as Rev. Dr. Otis Rice and Rev. Dr. Paul L. Tilden of the Department of Pastoral Service of the National Council of Churches. These eminent professional men have under their supervision the Commission on Religion and Health.

Also, I owe a debt of appreciation to my medical brother, Dr. Robert Clifford Peale of Olean, New York and to my esteemed associate, Dr. Smiley Blanton, Executive Director of the American Foundation of Religion and Psychiatry, and to Dr. Iago Galdston of the New York Academy of Medicine, for their insight into the important relationship of the physician and the pastor.

It is a high privilege to appear tonight on "Medicine's Proclamation of Faith" program upon the occasion of the inauguration as President of the American Medical Association of one of the most eminent men in your profession, Dr. Elmer Hess. I have followed the thinking of Dr. Hess and have admired him not only for his professional competence, but also for his keen insight into the place of the spiritual in the healing art and for his forthright enunciation of his positive convictions.

Clergymen hold the Doctor of Medicine in high esteem, not only as a scientist, but also as a servant of God who is called to a task no less sacred than their own. Does not the physician deal with the body, which is the temple of the soul? Moreover, since it is now recognized that sickness and health are not infrequently related to states of mind, the functions of the clergyman and the physician actually seem to draw more closely together. Of course, the clergyman scrupulously avoids infringing upon the sphere of the physician, his desire being only to help the patient in such a manner as may seem proper. Tonight's program is an event of far reaching significance when the great American Medical Association calls the attention of the nation to the importance it ascribes to faith in the practice of medicine. Clergymen, as well as the public, generally give sincere thanks to God for American medicine under our American freedom. Here in this climate of faith and freedom medicine is ever reaching new heights of achievement and new ability to serve humanity.

WORKING TOGETHER

Symbolic of this progress is the increasing cooperation of doctors and ministers, based as it is on the recognition that man is soul as well as body. It seems rather generally accepted currently that there are physical symptoms which are actually employed by the total personality to express emotional disturbances or even spiritual needs. Therefore, treatment of the physical symptom is apt to be more effective if the emotional or spiritual need is concomitantly cared for. This specifically calls for understanding cooperation between two types of professional competence, the physician and the clergyman.

An illustration is the case of the middle aged businessman who evidenced symptoms suggestive of a stroke. Formerly active, even dynamic, he became extremely lethargic. His mental and physical reactions slowed down. His physician concluded that the basic trouble lay in the spiritual field. Ultimately, a catharsis

---

Pastor, Marble Collegiate Reformed Church, New York.

This address was presented at the inaugural ceremonies at which Dr. Elmer Hess was installed as president of the American Medical Association, Atlantic City, N. J., June 7, 1955.

of the mind was brought about in which he emptied out a mass of hate and guilt that had accumulated over a lengthy period. This had stimulated a chronic fear and had developed a profound depression. Apparently both body and mind conspired in an effort to effect a retreat from life. He complained of insomnia, among other difficulties, and we asked how he expected to sleep well with two such annoying bedfellows as anxiety and guilt. It came out that he was involved with a married woman who threatened to expose him to her husband if he broke off their illicit relationship. Since he was a respected citizen in his small community, this meant ruin and he lived in perpetual terror. However, we encouraged him to sever this evil relationship regardless of consequences. When the weight of guilt and fear was lifted through confession and divine forgiveness, the symptoms left him and he returned to an apparently normal state, except for a residual tension problem which is gradually being reduced by medical treatment and the therapy of right thinking.

One of the greatest physicians with whom I have worked exemplifies this ability, as a godly doctor and a thoroughly consecrated layman, to mediate spiritual values upon occasion with medical procedure. This physician is a former missionary doctor. So profound is his understanding, so skillful his science, so spiritual his character, that if I were approaching the end of my own earthly life, I would be content to have the benefit of his services, both as doctor of the body and physician of the soul. In both personality and scientific skill, he is an excellent example of what we might call the priesthood of the laity.

WOMAN HELPED BY FAITH

A woman patient had been consulting this doctor regularly, showing him a spot, always asking in terror, "Is it cancer?" On her fiftieth birthday, she repeated the question. He studied her, then said, "Today you are fifty, and for years your full happiness and well-being have been frustrated by your fears. Now is the time to get free from them." She then revealed a previously untold childhood experience, which proved to be a source of her trouble. At eight years of age, her sister, a beautiful girl, had died. She, however, had been rather plain, and her mother complained bitterly as she stood by the casket, "Why wasn't it you?" This rejection and severe wound of the ego produced a hatred of her mother, which she had unconsciously carried all these years. Also, an unconscious feeling of unworthiness developed. The doctor, realizing the emotional and spiritual operation that needed performing, encouraged her to empty out her hate and mental suffering. He then prayed with her, that God would grant her peace. While the required change in thinking was not easily attained, she has become, so he reports, a much healthier and more normal person. It should be added that in usual circumstances, this physician uses the clergyman where spiritual treatment is indicated.

PRESCRIPTION FOR LIVING

Another doctor with whom I am closely associated keeps books of a spiritually inspiring nature on his waiting room table. On another table are the usual selection of magazines. The office nurse who keeps careful watch, told me that by far the largest number of patients read the books. This doctor has often prescribed such reading as a part of his treatment, and with good effect. I have known a number of physicians to write as a prescription the reading of certain books on right spiritual thinking. These prescriptions were filled at the book store, rather than the drug store.

God heals in two ways: through his servants, the practitioners of scientific medicine, and through his servants, the pastors, practitioners of sound faith. And it may well be added that while faith partakes of the philosophical and theological, yet the spiritual laws of the Bible demonstrate an exactitude when believed and practiced that suggest characteristics of an exact science. Science may be described as a mechanism for the transmission of power through law. Religion meets that test when its workable formulas are used as a way of life. The combination of God and the doctor—i. e., the physician who treats and God who heals—is no less a religious process than the cure of souls or the cooperative function of God and the pastor. The pastor treats and God heals the deep lesions and maladies of the soul life.

ROLE OF FAITH

Recent work dealing with the effect of stress on the body would seem to further bring together the disciplines of religion and medicine, since the effect of prayer, faith and love in healing those mental states that stimulate tension is widely known. Jesus Christ, called the Great Physician, spoke much of health and healing. While He did heal physically, His chief emphasis was that right thinking and religious living lead to holiness, another word for wholeness or well-being.

In addition to the contribution of the physician, the work of the pastor in bringing to the patient the calm certainty of faith, the knowledge of prayer, an intellectual basis for belief, the healing power of love and release from sin is efficacious in reducing and controlling stress.

A New York physician sent us a patient whose problem was stress. He had given proper treatment, but was unable to get a satisfactory result. He made an effort to probe deeper level emotional and spiritual attitudes, but the patient resentfully declared that his morals had no relation to his physical condition. But the physician thought they did and suggested that he consult me as a pastor. It finally came out that the patient, as he himself described it, had been "siphoning off money" from an estate he was managing for the adolescent son of his deceased brother. He had attempted to rationalize his thefts, but finally admitted his wrongdoing. He sought and received forgiveness and began the process of restitution. So deep was his relief upon his mind being cleansed of this guilt that the physical stress manifestations greatly improved.

The physician commented that "he couldn't heal the body until the soul had been healed, and that the stress in this case was a symptom of the ill health of guilt." This, of course, is not to imply that all stress has such cause, for the pressure, responsibility and general tension of our time are profoundly contributing factors. In all these matters, the healing of the peace of God may be mediated through a dedicated doctor and clergyman, each working within his own field, and yet in cooperative understanding.

SERVANTS OF GOD

The physician is surely one of the most beloved figures in America. When sickness comes, the arrival of the doctor brings hope and comfort. To him, people look for healing and deliverance from pain and fear. "Everything is all right; the doctor is here" is said with relief and love. What a privilege to enter with such affection into the lives of human beings.

The clergyman, who himself is intimately associated with men, women and little children in the deep experiences of their lives, salutes with faith and esteem those great servants of God and humanity, the doctors of America.

1 W. 29th St. (1).

Swallowed Foreign Bodies.—The symptoms of swallowed foreign bodies are usually minimal and there is a long latent period between the incident of swallowing and the onset of clinical signs of complication. A good history and a high index of suspicion are the most important facets leading to a correct diagnosis. A patient's statements concerning swallowed objects should not be regarded lightly. Examinations of roentgenograms by the physician immediately responsible for the patient's care is most important. Unexplained fever, pain, or roentgenographic findings should be carefully investigated. Repeated studies and examinations are often necessary to identify the presence of a foreign body. Only a few patients need be subjected to surgical removal of the foreign body, because most objects which have reached the stomach will pass on through the gastrointestinal tract. Surgical intervention should not be instituted on the basis of the history alone, but rather on the evidence of peritonitis, obstruction, or lack of progression of the foreign body through the gastrointestinal tract. In patients needing operative removal, the procedure is usually accomplished easily.—Col. R. T. Gants (MC), U. S. Army, and Major J. B. Jay (MC), U. S. A. F., Foreign Bodies in the Gastrointestinal Tract, *United States Armed Forces Medical Journal,* July, 1955.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Malpractice: Physician's Liability for Negligent Nursing Procedures.—The plaintiff sued for injuries to his hands allegedly resulting from the negligence of the defendant physicians. From a judgment in his favor, the physicians appealed to the Supreme Court of Pennsylvania.

The plaintiff had been a mental patient in the Allentown State Hospital since 1943, suffering from manic depressive psychosis. This illness is characterized by fluctuations from periods of depression, worry, and loss of weight, to periods of overactivity, lack of restraint, and excitability. Part of the time the patient may seem entirely normal, and his emergence from one mood to another may occur suddenly. During the overactive period the patient, in common language, is a raving maniac. In May, 1946, the plaintiff escaped, and when he was returned by the police on the following day he was in this violent manic state. One of the defendants ordered a wet pack to be administered, and the order was followed. Later a nurse reported that the plaintiff was physically fit but still violent, so a second wet pack was ordered. After that, the supervising nurse was told to continue with the wet pack treatments as long as the patient remained violent but physically fit. Altogether, three wet packs were given.

The wet pack treatment is administered to patients whose mental condition renders them violent. This treatment is a means of both calming them emotionally through the therapeutic effects of warm water and restraining them from violence. Such treatment is administered in the following manner. Sheets, usually six, are immersed in water. They are then wrung dry; the arms are separately wrapped and the sheets then wrapped around the body and the arms and legs, so that the patient is completely swathed in sheets from his head to the tips of his toes. Two sheets are used as ties, one placed about the body and arms in the region of the elbows and tied, and the other is tied above and below the knees. The patient is able to move his limbs but he cannot free himself. He is then immersed in a tub of water, the temperature of which is controlled by a thermostat at about 94 to 96 degrees. He is kept in the water for a period of approximately six hours. When he is taken out, the sheets are removed, and his body is bathed and rubbed with oil or grease. Fresh sheets are then applied, and he is again immersed in the water. Generally the patient receives a series of these treatments, the number and duration of which depend upon his mental and physical condition.

Neither of the defendants took any part in the administration of these treatments. While the treatments are given only on order of the physician, their administration—that is, wrapping the patient in sheets, immersing him in water, checking the water temperature, checking the pulse and respiration, observing him, and reporting thereon to the physician—is strictly a nursing procedure and is performed only by the nurses and attendants. At no time are physicians present or required to be present unless the reports from the nurses and attendants indicate a necessity therefor. Dr. Goshorn was the plaintiff's expert on the subject of method of administering wet packs. Both on direct and cross examination he reiterated that its administration is entirely a nursing procedure and that the physician is never present or required to be and that he relies on reports from the nurses. Dr. Goshorn testified that the mental condition of the plaintiff might require continuing the treatment without regard to the physicial condition. His opinions were based on 23 years of experience. Not a single person, physician, or layman, appeared to contradict the evidence, or to deny that it was the standard practice, or to state that it was improper, or that it was not in accord with the best practices of the profession.

After the treatments the patient's hands swelled and blistered, became infected and deformed, and lost 60% of their normal function. The plaintiff contended that such injuries were the result of the defendants' negligence in failing to properly supervise the administration of the packs and in opening some of the blisters with a knife, which one of the defendants carried in his pocket.

The duty imposed by law on the defendant physicians is the employment of such reasonable skill and diligence as is ordinarily exercised in their profession, giving due regard to the advanced state of the profession at the time of treatment. It has been uniformly held that expert testimony is necessary to establish negligent practice in any profession. What the lower court decided and what was determined by the jury was not whether the defendants had been guilty of negligence in following the well-recognized and established mode of treatment but rather whether the mode of treatment was proper. It was shown in the face of testimony produced by the plaintiff's own experts that the treatment and methods employed were of long-standing both in the Allentown State Hospital and elsewhere. Thus, the court permitted the jury of laymen, without knowledge of these practices, to say that a treatment was improper, which expert witnesses said was in accordance with the accepted practice.

In the instant case the plaintiff failed to show by any expert testimony just what Dr. Risser should have done or refrained from doing. From the circumstances that a verdict was recovered, the inference is that Dr. Risser should have been present and that he should have examined the plaintiff between each pack and during the course of them. The testimony of all the experts called on either side of the case was that this requirement was not a part of the standard and accepted practice. It is also the general rule that a physician is not liable for injury to a patient, where such occurs as a result of nursing procedures, said the Supreme Court.

So far as injuries resulting from the breaking of the blisters with a pocket knife, the court said that there is no evidence that the use of the nonsterile knife could have produced the injuries to the plaintiff, or indeed contributed to them. The plaintiff's only expert on this phase of the case, Dr. Marcks, stated that he did not "believe that infection had a thing to do to contribute to the development of the deformity (of the plaintiff's hands)"; and he testified that "the use of unsterile instrument" to open blisters as mentioned might contribute or be a contributing cause to infection but not be a contributing cause to the deformity the plaintiff had. The testimony of Dr. Marcks was plainly insufficient to charge Dr. Daley with negligence in that it failed to show the connection between the injury resulting from the negligent act and a later condition.

Accordingly, the judgment of the trial court in favor of the plaintiff was reversed, and judgment was entered for the defendant physicians. *Powell v. Risser, 99 A. (2d) 454 (Penn., 1953).*

Paternity Tests: Results Must Exclude Paternity.—The plaintiff started a bastardy proceeding against the defendant. The trial court entered a judgment for the plaintiff, and the defendant appealed to the superior court of New Jersey, appellate division.

The trial court, pursuant to state statute, directed Dr. Phillip Levine to perform blood-grouping tests on the plaintiff, her child, and the defendant. The state statute authorizing such tests permits the expert who gives the tests to testify only if the results show a definite exclusion of paternity on the part of the defendant. At the trial Dr. Levine was asked by the court if the instant tests showed exclusion. He responded that on the assumption that the plaintiff had a very rare and unusual serologic make-up the tests did show exclusion. The court then refused to permit Dr. Levine to testify as to the results of the tests, even though, when the pertinent statute was enacted in 1939, the problem of an unusual serologic make-up, which Dr. Levine had in mind, was unknown to medical science.

The superior court held that the trial court correctly applied the statute law, which forbids using the results of blood grouping tests as evidence, except where such tests definitely establish exclusion. The court said that the admission of testimony by Dr. Levine concerning the effect of such tests of the serologic make-up of the plaintiff would, in effect, either constitute an exception to the statute or permit testimony discrediting the finding of exclusion. Whichever would be the effect of the testimony, the result would violate the statute and amount to judicial legislation. The judgment for the plaintiff was therefore affirmed. *Miller v. Domanski, 97 A. (2d) 641 (N. J., 1953).*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Further Evidence That Hyperthyroidism (Graves' Disease) Is Not Hyperpituitarism: Effects of Triiodothyronine and Sodium Iodide. S. C. Werner, M. Spooner and H. Hamilton. J. Clin. Endocrinol. 15:715-723 (June) 1955 [Springfield, Ill.].

The effects of triiodothyronine and of thyrotropin were observed in patients with active hyperthyroidism, euthyroid patients with ocular signs of the disease, patients in sustained remission from the disease, and euthyroid control subjects. The failure of triiodothyronine to depress thyroidal radioiodine uptake in the patients with hyperthyroidism provides indisputable evidence that the normal reciprocal pituitary-thyroid relationship is disrupted in this disease. The 2 mg. daily doses of the drug were the approximate equivalent of 2.6 to 3.2 gm. of thyroid daily, and caused enough clinical exacerbation of the hyperthyroidism to necessitate stopping treatment after six days. The concept is thus untenable that hyperthyroidism is due to a pituitary "thermostat" set to maintain too high a blood level of thyroid hormone but functioning normally at this new level. The failure of the pituitary to be suppressed by either thyroid or triiodothyronine also makes untenable the alternative possibility that the pituitary becomes hyperactive because the thyroid in hyperthyroidism secretes an abnormal thyroid hormone that cannot suppress the pituitary. No abnormal secretion has been found in hyperthyroidism. A striking amelioration of hyperthyroidism was produced by the administration of sodium iodide. The recovery, if occurring in the presence of an excess of thyrotropin, would necessarily imply interference with the effect of thyrotropin, but when small doses of thyrotropin were given, the release of thyroid hormone was great enough to suggest an increased sensitivity to the hormone. Thus the evidence suggests that no excess of thyrotropin is present in hyperthyroidism and that hyperpituitarism is not the causative factor. That the thyroid gland has an intrinsic mechanism, not under pituitary control, for trapping iodine and regulating the extent of this trapping during iodine lack has recently been demonstrated in the hypophysectomized rat. Derangement of such a mechanism could result in hyperthyroidism, as could a derangement of other extrapituitary processes which, in turn, might control this mechanism or those as yet unknown. As a corollary, the study suggests that iodides do not act in hyperthyroidism by inhibiting the effect of thyrotropin, but rather act directly on the overactive thyroid cell, partly at least, by inhibiting the release of thyroid hormone. The use of triiodothyronine was found to have great diagnostic value, since failure of suppression of thyroidal uptake is indicative of hyperthyroidism.

Lipoid Pneumonia. A. O. Hampton, C. E. Bickham Jr., and T. Winship. Am. J. Roentgenol. 73:938-949 (June) 1955 Springfield, Ill.].

In 35 patients between the ages of 3 months and 86 years with lipid pneumonia, the causative agents included animal, vegetable, or mineral oil. After either oral or nasal administration of oily material, portions of it remain adherent to the pharyngeal mucosa and sometimes drain into the trachea. If this is repeated, enough oil may collect in the alveoli to produce pathological changes. In 22 patients lipid pneumonia was produced by the voluntary ingestion of mineral oil to combat constipation, in eight patients by nose drops, in two infants by milk and cod liver oil, and in one patient by petroleum jelly. No history of oil ingestion was obtainable in the remaining two patients. Cough, dyspnea, and chest pain were the most frequent complaints. The most common physical findings were dulness to percussion, harsh breath sounds, and bronchovesicular or bronchial breathing. One patient showed pulmonary osteoarthropathy. A low grade fever was present in several of the patients with diffuse disease. Roentgenologic examination revealed densities produced by the disease that varied in their size, shape, and location. They could be classified as diffuse or nodular. The diffuse group, occurring in 24 patients, was characterized by diffuse, fine, linear, spun-glass-like densities, the periphery of which sometimes was fairly sharp but more commonly faded out into the lung fields. These densities were clustered together, and intermingled with them were areas of rarefaction representing aerated lung. The general impression gained from these densities was that of fibrosis. There were 11 patients in the nodular group. The nodules were characterized by rather homogeneous, soft tissue densities varying from several centimeters in diameter to very large masses. The borders in some cases were sharply defined, but in others they were irregular with extension of fine projections into the adjacent tissues. The large lobulated masses were apparently due to coalescence of multiple smaller areas. A definite diagnosis of lipid pneumonia could not be established from the roentgen appearance alone. Bronchography was performed in 12 patients, and the most common finding was obstruction of the terminal bronchi in the involved area. Both lungs were involved in 21 patients, and of the 14 with unilateral involvement, the disease was on the right side in 12 and on the left side in 2. The nodular areas were usually single, but multiple areas were not uncommon and different lobes were involved. Nine of the 35 patients were operated on for lesions that simulated tumor, and autopsies were performed on all 10 patients who died of the disease. In these patients the diagnosis of lipid pneumonia was proved by the visualization of large amounts of oil in tissue sections. The nodular and diffuse types of lipid pneumonia were quite similar histopathologically. In the early phase of the disease most of the alveolar lining cells were cuboidal and the alveoli contained partially phagocytosed oil. In the late stages, large segments of functioning lung were replaced by fibrous tissue containing aggregates of lymphocytes, small oil droplets, and scattered plasma cells. Most of the alveoli had disappeared. The diagnosis of lipid pneumonia in the living patients was made on the basis of a history of oil ingestion, consistent roentgenographic findings, and the presence of intracellular oil in the sputum. No therapeutic measures are known for the removal of significant amounts of intra-alveolar oil. Patients who develop symptoms should be advised to stop medication. Three of the authors' patients improved clinically after discontinuance of oily medication. The best treatment is prevention.

Etiology of Esophageal Carcinoma. J. Mosbech and A. Videbaek. J. Nat. Cancer Inst. 15:1665-1673 (June) 1955 [Washington, D. C.].

Of 169 patients with esophageal carcinoma, 68 were unsuitable for inclusion in this analysis because of uncertain diagnosis or inadequate family histories. The remaining 101 patients included 83 men and 18 women. The investigation did not reveal a greater number of cancers of the esophagus or of other sites among the relatives of patients with esophageal cancer than among the relatives of normal controls. The study thus failed to show any influence of hereditary factors. Consequently cancer of the esophagus seems to be chiefly due to exogenous factors. The marked preponderance of men suggests that men are more exposed to the exogenous carcinogenic action. Abuse of alcohol seems to be an important causal factor in esophageal carcinoma, at least in men. Sixty-five per cent of the patients had been alcohol addicts, and 21% had been exposed to alcohol

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

in their occupations. The incidence of syphilis was not greater in the patients with esophageal cancer, and none had sideropenic dysphagia. Data on eating habits were inadequate to provide conclusive evidence that eating hot food could be a causal factor in esophageal cancer.

The Tuberculosis Patient Who Leaves Against Medical Advice from the San Francisco City and County Hospital. H. A. Wilmer. Dis. Chest **27**:597-623 (June) 1955 [Chicago].

Of 751 patients with tuberculosis who were discharged from the tuberculosis department of the San Francisco City and County Hospital in 1952, 520 were discharged regularly, and 231 (30.7%) left against medical advice. Of these, 131 (17.4%) signed a release, 82 (10.9%) went absent without leave (AWOL), and 18 (2.4%) were disciplinary discharges. Seventy-four of the 231 patients were compared statistically with 69 control patients in an attempt to define what characterizes the self-discharge group from medical and social viewpoints. Most of the self-discharge patients had far-advanced tuberculosis but most of the control patients did not. There was no sex difference between the total number of self-discharge patients and the total number of control patients. The female self-discharge patients had a significantly greater incidence of positive sputum than the male self-discharge patients. The male AWOL patients had a significantly greater incidence of positive sputum than the female AWOL patients. There was a highly significant increase in the extent of the disease among readmitted self-discharge patients compared with all first admissions. Most of the self-discharge patients left the hospital within six months. Most of the AWOL patients stayed less than three months. Most of the patients who signed a release stayed more than three months. The self-discharge patients left sooner than the controls. There was a decrease in number of self-discharges during the summer months, which was statistically significant. Most of the self-discharge patients were separated or divorced, but most of the control patients were married. This was highly significant statistically. A history of alcoholism was obtained three times more often in the self-discharge patients as compared with the controls. In the AWOL patients the alcoholics predominated, while in those who signed a release the nonalcoholics predominated. These too were significant differences. It is estimated that the cost of hospitalization to the city, county, and state for 184 self-discharge patients of the tuberculosis department was $217,375. In their projected cost based on readmission figures it was estimated that the self-discharge group over a five year period represents a financial liability in excess of $1,250,000. If the self-discharge group were reduced by one-fourth, the savings in hospitalization would amount to $54,343 a year, or over $250,000 in five years. If it were possible to define the patient population at risk from the standpoint of self-discharge, it would be possible to compare the changes in risk factors over a period of time and in relation to adjustment of program. The lack of statistical controls of such an important part of the tuberculosis program should spur students of the problem to extensive studies.

Incidence of Postvaccinal Encephalitis After Subcutaneous Vaccination Against Smallpox in Persons of Various Age Groups Vaccinated for First Time. K. Berger and F. Puntigam. Wiener med. Wchnschr. **105**:405-408 (May 21) 1955 (In German) [Vienna, Austria].

The Austrian federal law concerning vaccination against smallpox, which was enacted in 1948, permits the use of the subcutaneous and intracutaneous vaccination techniques besides the cutaneous method. Of 404,524 first vaccinations that were successfully performed between 1949 and 1953 only 5,001 were performed subcutaneously and 733 intracutaneously. The authors used the subcutaneous technique, which has several advantages over the cutaneous technique: secondary infections of the vaccination area do not occur, there is much less risk of secondary or transmitted vaccinia, the resulting vaccinia runs a milder course, care of the vaccinated persons is simpler, and no disfiguring scars are produced; but the subcutaneous technique has the disadvantage that the immunity produced lasts only four to six years. About 10,000 subcutaneous vaccinations were performed up to the end of 1953. Of these, five led to postvaccinal encephalitis that was fatal in two patients. All five patients were over 3 years of age. The risk of encephalitis in patients over 3 years of age who were vaccinated subcutaneously was significantly greater than that in persons under 3 years of age vaccinated cutaneously or subcutaneously. The authors caution against the use of the subcutaneous method for first vaccination against smallpox in children over 3 years of age as well as against first vaccination by the cutaneous method in children beyond this age limit. The subcutaneous technique is less suitable for general vaccination because of its reduced immunizing effect. It should be used only in single cases in which for some reason it appears desirable to place a lesser burden on the vaccinated person, and subsequent cutaneous vaccination should be recommended in these cases.

Psychologic Barriers to Rehabilitation of Cancer Patients. A. M. Sutherland. Postgrad. Med. **17**:523-526 (June) 1955 [Minneapolis].

Rehabilitation is the process by which the survivor of an experience damaging to body or mind is restored as closely as possible to his previous level of activities. It is not generally recognized that unsuccessful attempts at rehabilitation of the cancer survivor are more often due to his own psychological and emotional problems than to physical and environmental factors. Most survivors are physically able to resume their usual occupations or activities. There are many little adjustments to be made in the patient's lifework, recreation, and marriage. Levels of activity in these areas do not necessarily fluctuate together. One man returns to work at approximately his preoperative level but restricts social or sexual activities. Another is forced to work full time, but he does so only at the cost of increased anxiety and the development of conversion phenomena and physiological disturbances. Another shifts his employment to a less demanding job. When work is restricted for other than physical reasons, two main sources can usually be identified: (1) hypochondriacal notions of body injury and fragility, and (2) fears of unacceptability to others. The sense of body injury is supported by misconceptions of the physiological role of the sacrificed organ in the intact body. A number of patients who have undergone a colostomy state that the loss of the rectum must inevitably affect their digestive or absorptive powers, or that irrigation washes out nourishment as well as feces. Loss of the uterus and menstruation, with or without oophorectomy, may be thought to herald old age and depleted vitality. Restriction in social contacts is frequently due to a sense of unacceptability to others who are not expected to accept the change in form, as after mastectomy, or the possibility of uncontrolled function, such as occurs after colostomy. Patients who have undergone a total gastrectomy fear that intestinal hypermotility may be audible or cause embarrassing symptoms. Decreases in sexual activity may also be expressive of emotional disruptions. In men, it may follow operations on sites far removed from the genital tract, such as thoracotomy or laryngectomy. The man usually regards this activity as too taxing. Sexual restriction in women may be associated with fears of injury and with hypochondriasis. Paranoid reactions, sometimes frankly delusional, are serious barriers to rehabilitation. They are commonly directed against the physician or other medical personnel and are very resistant to treatment. The patient's spouse may greatly help or hinder rehabilitation, and a good patient-physician relationship is the best guarantee against the development of crippling beliefs and their expression in unnecessary restriction of activities.

Treatment of Iron Deficiency Anemia. D. H. Coleman, A. R. Stevens Jr. and C. A. Finch. Blood **10**:567-581 (June) 1955 [New York].

In the normal person the amount of iron absorbed by and lost from the body is exceedingly small. There are certain periods during life, i. e., infancy, adolescence, and pregnancy, when body iron requirements are increased; the most important of these is infancy. Here, existing iron stores are rapidly depleted, and a deficient diet can soon produce iron deficiency. Once a full complement of body iron has been accrued, the adult is independent of iron intake and becomes iron deficient only through blood loss. In the production of iron deficiency, iron stores are exhausted before anemia appears. If any question in diagnosis from usual laboratory tests exists, the direct examination of marrow for hemosiderin will establish the diagnosis. It is of obvious importance to confirm the diagnosis by specific therapy and to determine the cause of the iron depletion. Response to orally given iron therapy is highly predictable; failure of response usually indicates a mistaken diagnosis. In a small but significant group of patients unable to take iron because of gastrointestinal symptoms, unable to absorb iron, or in need of iron reserves parenteral administration has distinct advantages. The saccharated oxide of iron is an effective preparation for this purpose.

"Coughing Disease," Equivalent of Allergy: Its Significance in Practice; Preliminary Information. E. B. Salén. Acta allergol. 8:228-230 (No. 3) 1955 (In French) [Copenhagen, Denmark].

Coughing and throat-clearing occurring early in the morning and lasting until the patient gets up was noted in 11 patients. It is more disturbing to those around him than to the patient himself, as shown by the fact that the wives of two of the patients in this series threatened divorce. The disorder appears to have an allergic basis, but the sensitizing agent is difficult to discover. In two instances it was proved to be house dust. Coughing disease seems to be endemic to the northern countries; the author believes it is a preliminary form of asthma activated by climatic factors. Eosinophilia has been found in some patients. The patient's general condition is good except for some insomnia, and there are no physical signs of asthma or bronchitis. No case has as yet progressed to asthma. Total suppression of symptoms was obtained in the two patients mentioned above by strict elimination of house dust and nonspecific antiallergic therapy with allergol.

SURGERY

Vagotomy, Hemigastrectomy and Gastroduodenostomy (Finney-Von Haberer) in the Treatment of Duodenal Ulcer. R. J. Coffey and E. J. Lazaro. Ann. Surg. 141:862-871 (June) 1955 [Philadelphia].

To evaluate the relative resistance to experimentally produced peptic ulcers of hemigastrectomy with and without vagotomy and with both gastrojejunal and gastroduodenal anastomoses, experiments were carried out in adult dogs. Results indicated a high resistance of the animals that had undergone hemigastrectomy and gastroduodenal anastomosis to the ulcer-provoking influence of histamine in beeswax. The relative vulnerability of a gastrojejunal anastomosis after hemigastrectomy became clearly apparent. Interruption of the vagus nerves conspicuously lessened the incidence of histamine-provoked ulceration, while preservation of the excluded gastric antrum and diversion of the alkaline bile and pancreatic juice away from the duodenum increased the incidence of experimentally produced peptic ulcers. Vagotomy combined with hemigastrectomy and end-to-side gastroduodenostomy was employed as a routine procedure in the surgical treatment of 80 patients with duodenal ulcer. Fifty-five of the 80 patients were followed postoperatively for a sufficiently long period to justify a preliminary report of the results. The pH of the gastric juice varied between 4.5 and 7 postoperatively, and free hydrochloric acid was absent in all but one patient. In one patient, in whom incomplete vagotomy was shown, a pH of 2 and free hydrochloric acid of 70% was present. The appetite was stated to be excellent or good in 48 patients and only fair in 7. Seven patients continued to consume a bland diet, but the remainder consumed an unrestricted diet. Of the 12 patients whose preoperative weight was below ideal, 11 had gained weight postoperatively to a level of or beyond their ideal weight. Of the 42 patients whose preoperative weight was above ideal, only three were below ideal weight postoperatively, but in the remaining patients the postoperative weight remained above ideal. Not one of the patients died. Gastric retention, necessitating a feeding jejunostomy, occurred in a single patient. Postoperative hemorrhage required reoperation in only one patient. Secondary closure with the aid of anesthesia was required in two patients with dehiscence of the abdominal wound and hemorrhage. Mild wound infection occurred in two patients. Phlebothrombosis of the left leg occurring in one patient responded promptly to anticoagulant therapy. A recurrent duodenal ulcer developed in a single patient. A mild dumping syndrome occurred in four patients, persisting for one to four months in three patients and for two years in one. A severe dumping syndrome persisted for 20 months in a single patient. Mild intermittent diarrhea occurred in five patients, dysphagia in two. A hemoglobin level less than 12 gm. per 100 cc. was observed in only one patient. Both experimental studies and the follow-up in the authors' 55 patients revealed certain conspicuous advantages of the combined procedure of vagotomy, hemigastrectomy, and end-to-side gastroduodenostomy in the treatment of duodenal ulcer.

A Critical Evaluation of Radical Subtotal Gastric Resection as a Definite Procedure for Antral Gastric Carcinoma. H. W. Mayo Jr., J. K. Owens and M. Weinberg. Ann. Surg. 141:830-839 (June) 1955 [Philadelphia].

Of 194 patients in whom a diagnosis of carcinoma of the stomach was made between 1940 and 1953, 64 were not operated on, 77 underwent operations other than resection of the stomach, and 53 had resections of the stomach. In 22 of the 53 patients, the resections were classified as curative; this classification was made if the lesion was limited to the stomach and the immediately adjacent regional lymph nodes, if there was no invasion of adjacent organs or evidence of distant metastases, and if there was no evidence that tumor tissue had been left behind at the operation. In the remaining 31 patients who had resections classified as palliative procedures, 4 had scirrhous carcinoma, 3 acute free perforations, 3 distant metastases or irremovable involved lymph nodes, and 21 involvement of adjacent organs. In 129 of the 194 patients in whom a diagnosis of carcinoma of the stomach was made, this was done five or more years before the authors' study was made. Ten of these patients survived five years or more, an over-all survival rate of 8%. Of the 53 patients who underwent resections, 20 (39%) survived for five years. Ten (67%) of the 15 patients in whom no lymph node involvement was shown survived five years or more; in 9 of these 10 patients the lesion was in the antrum. None of the 11 patients with lesions of the antrum in whom lymph node involvement was shown survived for five years. Radical subtotal gastric resection, as presently employed, appears to be inadequate to save the lives of those patients with antral carcinoma that has already metastasized to the regional lymph nodes. In view of the sites of metastasis and recurrence noted in the authors' study and in the studies made by other workers, total gastrectomy appears to have little to offer for these patients. Consequently, the procedure originally proposed by Harvey, which combines pancreaticoduodenectomy with radical subtotal gastric resection, is suggested as a possible approach in an effort to increase the survival rate of patients with antral carcinoma with lymph node metastases.

Surgical Experiences with 316 Duodenal and Marginal Gastric Ulcers. R. M. Bolman and R. P. Lloyd. A. M. A. Arch. Surg. 70:833-842 (June) 1955 [Chicago].

The authors present their experiences in 341 operations on 316 patients with duodenal and marginal gastric ulcers. The only marginal gastric ulcers considered here are those for which they themselves had performed the original operation. Gastroenterostomy and vagotomy was performed in 216 patients. Eleven of these had recurrences, all of whom were relieved by gastric resection. There were no deaths in this group. A second group of 12 patients was subjected to transthoracic vagotomy alone as definitive treatment for duodenal ulcer. These patients all had their primary operations in 1946. Seven of the 12 were subsequently treated by gastroenterostomy, because of gastric stasis, vomiting, and fulness. Gastric resection, colon resection, and repair were performed on one patient in whom a marginal ulcer with gastrojejunocolic fistula developed after vagotomy. Two of the vagotomy group have mild stasis symptoms not justifying additional surgery. No deaths occurred in this group. The third group of 88 patients were treated by conservative (50%) gastric resection and vagotomy. There have been no recurrences and no deaths in this group. Surgical opinion is still rather sharply divided between radical resection on the one side and vagotomy on the other. The authors themselves performed 112 high gastric resections with six deaths during the period when the aforementioned 316 patients were treated (without mortality) by vagotomy in combination with other measures. They believe that either high gastric resection alone or vagotomy and a drainage operation is inadequate surgical therapy. Since recurrences following resection depend on the presence of intact vagi and recurrences following vagotomy depend on the presence of the antrum, conservative (50%) gastric resection combined with vagotomy seems to be the operation of choice in the treatment of the duodenal ulcer diathesis.

Subtotal Gastric Resection with Colon Substitution: Reconstruction of a Neostomach Utilizing the Transverse Colon. D. H. Watkins and G. Wittenstein. A. M. A. Arch. Surg. 70:843-858 (June) 1955 [Chicago].

Seven patients had subtotal gastrectomy, and restoration of continuity was accomplished by the intercalation of a segment of transverse colon between the gastric remnant and the duodenum. Subtotal gastric resection (in the patients with duodenal ulcer) of 75 to 80% is an essential preliminary step to decreasing the gastric hypersecretion. The use of a segment of transverse colon makes possible a Billroth 1 type of reconstruction subsequent to gastric resection. The segment of transverse colon is ideally adapted anatomically to restore the crop function of the stomach. Food is held in the neostomach and delivered slowly to the duodenum. The immediate results suggest that the preservation of total duodenal function as an active factor in digestion is worth while. The result of the interposition of a segment of colon between the remaining gastric remnant, or, in the case of a total gastrectomy, between the esophagus and the duodenum, is that bile and the alkaline secretions of the upper small intestine are prevented from retrograde inundation of the lower esophagus to produce an alkaline esophagitis. This plan of using the transverse colon appears to be more circumspect than the use of a free loop of jejunum because of the susceptibility of jejunal mucosa to peptic digestion. The patient should be allowed up the evening of the day of operation, and the diet should begin with semisolid food, liquids being withheld until after the completion of the solid portion of the meal. Alimentation may begin as soon as flatus is passed by rectum. Many patients have symptoms of gastric delay or atony, which diminish gradually over the first three postoperative months. These symptoms usually appear as complaints of epigastric fulness and discomfort in the left upper quadrant, which improves spontaneously half an hour to an hour after the ingestion of the meal. Many patients find that they are unable to take cold liquids without precipitating epigastric cramps. In most patients the immediate postoperative status is improved by giving belladonna and other antispasmodics. No instances of the postgastrectomy "dumping" syndrome have been encountered.

Observations on the Surgical Physiology of the Human Liver Pertinent to Radical Partial Hepatectomy for Neoplasm. A. Brunschwig. Cancer 8:459-467 (May-June) 1955 [Philadelphia].

In some 50 excisional operations for primary and secondary hepatic neoplasms the author observed certain aspects of the surgical physiology of the liver that are pertinent to the excisional procedures that may be performed on this organ. In commenting on the question as to how much human liver may be resected he shows that hepatic tissue equivalent in size to a left lobe must be retained to ensure physiological function adequate for survival. Hepatic function tests are of limited significance in indicating physiological fitness for survival after partial hepatectomies. The essential independence of each hepatic lobe is demonstrated on the basis of a case history, in which it was shown that the liver is at least a major bilobed organ (there are smaller lobes) and that anatomic separation of each of the two lobes was all but accomplished without apparent hepatic disturbance or atrophy of one or the other of the separated lobes. That survival ensued further corroborated previous observations that one or the other of the major lobes may be resected with survival of the patient. The author believes that, while hyperplasia of hepatic parenchyma is possible in man, it occurs only on physiological demand and that the size of a mass of hepatic tissue does not indicate its physiological effectiveness. A gradual replacement of more than half the hepatic parenchyma by tumor results in a gradual shift of physiological load to the remaining uninvolved parenchyma. If this shift is slow, the remaining hepatic tissue can accommodate to the increased physiological demands without hyperplasia. Prior to major excisional surgery for hepatic neoplasms, a permanent reduction in vascularity of the liver compatible with life would, if feasible, have certain advantages, because hemorrhage is the most important immediate complication of such operations. Since gradual occlusion of the hepatic artery and of the portal vein have been shown to be feasible in the experimental animal, and gradual occlusion of the portal vein compatible with survival in man, the question arises whether or not gradual to complete occlusion of both these vessels with or without their definitive excision would possibly be followed by survival in man. An opportunity to observe this possibility presented itself in one patient whose history is presented. Failure of this patient to survive indicates that, in the absence of sufficient collaterals, simultaneous permanent occlusion and then resection of both portal vein and hepatic artery in the porta hepatis does not permit survival even though the preliminary occlusion of each was gradual. The multiple procedures necessary to devascularize the liver markedly are too complex for clinical application to man.

Surgical Treatment of Cancer of Colon: Report of Twelve Cases. R. Muñoz Kapellmann. Rev. invest. clín. 7:91-100 (Jan.-March) 1955 (In Spanish) [Mexico, D. F., Mexico].

Cancer of the colon requires early surgical treatment, consisting of resection of the tumor with ample resection of intestinal segments on both sides of the tumor, and of the portion of the mesocolon having metastases or the potentiality to metastasize. Extension of resection in cases of diffusion of cancer to nearby organs and structures depends on the site of the tumor in the ascending, transverse, or descending segments of the colon or in the hepatic or splenic curvatures. A primary anastomosis between the ileum and the transverse segment of the colon is feasible in resecting carcinomas of the right colon. Carcinomas of the descending segment of the colon should be resected in two-stage operations, with Mikulicz's modified technique and reestablishment of the intestinal lumen in the second stage of the operation. A palliative operation for resection of an obstructed segment of the colon is indicated in cases of nonremovable carcinoma causing acute occlusion. Resection is followed by direct anastomosis if feasible or else by permanent colostomy if direct anastomosis is not feasible. Fifteen patients were observed by the author between 1946 and 1953 in the Hospital de Enfermedades de la Nutrición of Mexico, D. F. Nine patients had a radical operation and three a palliative operation. Carcinoma was located in the right segment of the colon in five cases, in the transverse segment in one case, and in the descending segment in six. Nine patients had metastases. Two patients died in the postoperative period, from rupture of the suture in one case and an acute cardiovascular complication in the other. The remaining patients are well. Although the follow-up period is too short to allow conclusions, according to the literature the expectancy of survival after a radical operation for cancer of the colon is over three years in 32% of the cases and over five years in 25%.

NEUROLOGY & PSYCHIATRY

Electroshock Therapy in Patients over 60 Years. L. Michaux and A. Grasset. Rev. prat. 5:1531-1533 (May 21) 1955 (In French) [Paris, France].

The authors do not believe that advanced age is in itself a contraindication to electroconvulsive therapy. In 60 patients over 60 years of age, 478 sessions of electroshock therapy were administered. The only incident was an acromiocoracoid subluxation in a man of 65. The oldest patient was 84 years old. Advanced age is an indication for the exercise of special care in performing the examinations preliminary to electroshock therapy, especially as regards the circulatory system. Precautions must be taken before the period of convulsions against vertebral fractures due to spinal flexion. Oxygen is often administered to shorten the anoxic period after convulsions, and always to patients whose cardiovascular status is not perfect. In especially anxious patients electroshock is given under penthiobarbital narcosis. Electroshock therapy under curare is especially useful in hypertensive patients. Experience has shown that electroconvulsive therapy acts more rapidly on depressive syndromes in older patients than on those in younger ones. It seems that the more it impairs memory function the more effective it is. Involution melancholia is benefited more than cyclic melancholia; there too calming of anxiety is accompanied by rapid and deep perturbations in memory. Results in involution melancholia are purely temporary. The parallel action of electroconvulsive therapy on anxiety and memory probably indicates a causal relationship between these two. Shock therapy acts more rapidly in elderly persons because their memory is more fragile and can be more readily altered. Thus electroconvulsive therapy can be considered a method of cure or sedation by amnesia.

Effect of Prefrontal Interventions (Leukotomy, Topectomy) on the Psychic and Kinetic Manifestations of the Parkinsonian Syndrome. C. Gros, B. Vlahovitch and J. M. Enjalbert. Semaine hôp. Paris **31**:1831-1832 (May 26) 1955 (In French) [Paris, France].

Strong psychosomatic elements were present in two cases of paralysis agitans, in which the patients were benefited greatly by psychosurgery (bilateral prefrontal lobotomy in one and topectomy of areas 9 to 12 in the other). The operations affected both the mental state and the physical manifestations. The use of such operations should be limited to patients in whom psychic symptoms are prominent and the commoner forms of therapy of paralysis agitans are unsuccessful. Spiegel and Wycis were unable to ameliorate the condition of patients with pure dyskinesias by destruction of the dorsomedian nucleus. The specific mode of action of prefrontal intervention is not known.

Chlorpromazine Treatment of Mental Disorders. V. Kinross-Wright. Am. J. Psychiat. **111**:907-912 (June) 1955 [Baltimore].

An unselected group of patients admitted to the psychiatric service of a general hospital, and a lesser number of outpatients, 95 in all, were treated with chlorpromazine. Most of the patients received initially a minimum of 50 mg. of chlorpromazine intramuscularly four times daily. It is usually possible to switch to oral administration after a few days. Intramuscular administration is often painful and produces induration at the site of injection, particularly if the solution escapes into fatty tissue. The total daily amount of chlorpromazine may be increased by as much as 100 mg. until the optimum effect is achieved. Increasing familiarity with the effects of the drug has led to the use of larger doses. The average therapeutic dose for psychotic patients is about 800 mg. each 24 hours. In neurotic patients and in children treatment is started by the oral route and in doses as low as 30 mg. daily. Once improvement was manifested mediation was given only orally and progressively reduced over a eriod of weeks. In a few patients who showed a tendency to relapse larger doses were again given. Remission was obtained in 32 patients, great improvement in 36, slight improvement in 18, and no improvement in 9. Many patients were given maintenance doses of chlorpromazine on an outpatient basis and continued to improve. Chlorpromazine has low toxicity, even in large doses. It appears to be highly effective for controlling psychomotor excitement of all kinds without the undesirable effects of the standard methods and in maintaining the patient in a fairly accessible state at all times. Its action on other types of mental illness is not so remarkable but is worthy of further investigation, particularly in the chronic schizophrenic patients in whom most treatments are unrewarding. Facilitation of communication has occurred in many of this group. Speculation about the mode and site of action of the drug seems premature but evidence suggests that it is a subcortical one. Although in the initial states of treatment there is a resemblance in the behavior of these patients to those who have been lobotomized, there are none of the disadvantages found as a result of lobotomy.

GYNECOLOGY & OBSTETRICS

The Effect of Promethazine in Nausea and Vomiting of Pregnancy. J. P. B. Fitzgerald. New Zealand M. J. 54:215-218 (April) 1955 [Wellington, New Zealand].

To determine the incidence of nausea and vomiting, 254 antenatal clinic patients were interviewed. Consecutive cases, where the gestation had reached 24 to 32 weeks, were selected. Questioning was directed to find out whether nausea and vomiting had or had not been present. Of the entire group, 155 (61%) suffered from vomiting. Primigravidas were affected more often than multigravidas, 65.1 and 56.8% respectively. Most patients had taken some form of self-medication; none had received treatment from the antenatal clinic. Alternate patients were treated with Phenergan (promethazine hydrochloride), in a dosage of 25 to 50 mg. twice daily, and ascorbic acid tablets, 25 mg. twice daily. This latter substance was chosen since, as far as is known, it is inert as far as vomiting is concerned. Both forms of tablets were given for 14 days before the effect was assessed. Most patients were seen seven days after the start of treatment and some sooner. The effects were most striking in the mild cases. Of 22 such patients given promethazine, 20 said the vomiting had ceased, while of 25 given ascorbic acid only 6 said they were cured. In the group affected moderately, 23 out of 25 of the treated patients and 9 of 27 of the control group were cured or improved. In the severe group, 9 of 11 treated patients were improved or cured, but only 1 in 4 of the control group was. Of the 58 cases in the treated group 41 were cured, 11 improved, and 6 were unaffected. In the 56 controls 13 were cured, 3 improved, and 40 unaffected. These results show that promethazine has therapeutic value in vomiting of pregnancy. Discussing the possible causes of nausea and vomiting in early pregnancy and the mode of action of antihistaminic drugs, the author points out that recent work with chlorpromazine, a homologue of promethazine, has shown it to be a drug with only moderate antihistaminic qualities, but it has a depressant effect at the cortical and hypothalamic levels. Thus chlorpromazine produces emotional indifference and reduces emotional tension. It may be possible that promethazine exerts its beneficial effect on nausea and vomiting in the same way as chlorpromazine, as a central depressant rather than as an antihistaminic.

Tubal Pregnancy: Report of 37 Cases Seen from 1951 to August, 1954. C. Ouimet. Union méd. Canada 84:659-668 (June) 1955 (In French) [Montreal, Canada].

The author has noted an increase in the frequency of tubal pregnancies within the last decade. He attributes this to the use of antibiotics in the treatment of chronic pelvic inflammatory disease. Whereas in the past a patient was considered sterile after bilateral salpingitis, modern treatment has enabled such a patient to become pregnant. Although antibiotic therapy controls tubal infections, it does not restore the tubal mucosa to normal. Some inflammatory lesions remain that could alter the epithelium and produce changes in ciliary activity, causing tubal pregnancy by abnormal migration of the ovum. Of the 37 patients reported on by the author, 11 definitely had inflammatory lesions from previous salpingitis; others might well have been revealed by proper histological investigations. The diagnosis of tubal pregnancy must be made clinically; laboratory tests have only a relative value in the diagnosis. There are many variants in the clinical findings, leading to deviations from the classic description. For instance, eight (23%) patients in the present series had no history of delayed menstruation, vaginal bleeding (present in 85%) was not necessarily of a blackish color, and pain was sometimes dull rather than knife-like. Twenty-one of the pregnancies were ruptured and sequestered, nine were ruptured and constituted emergencies, and seven (two emergencies) were intact. Thirty-one patients were treated by salpingectomy and six by salpingectomy with ovariectomy. Salpingotomy is reserved for intact tubal pregnancy detected at the very beginning in a patient who has never had children and desires them, if the remainder of the tube is normal and the one on the opposite side is blocked. In this series the author also performed 15 appendectomies, 7 curettages, and 3 colpotomies. There were no deaths.

Pain Associated with Uterine Contractions During the Period of Cervical Dilatation. H. Pigeaud. J. méd. Lyon 36:421-426 (June 5) 1955 (In French) [Lyon, France].

There are two types of pain associated with uterine contractions during cervical dilatation, one physiological and the other pathological. The second type is commonly seen in women, especially primiparas, who are afraid of childbirth and are in a nervous, overexcited state. These pains are severe and have their severe character from the beginning of labor; they do not disappear during the period between contractions; and they occur in the lumbosacral region, which makes them difficult to tolerate. Cramps and muscular spasm are a prominent feature. In these cases, dilatation of the cervix progresses poorly. Such a pattern of pain constitutes a pathological event, since the course of delivery as well as the welfare of the parturient is influenced. There are two avenues of approach to the therapy of this condition: the combination of medical and obstetric techniques acting on uterine contractility known as "directed delivery" and prophylactic or curative analgesia acting on the nervous system and the routes of transmission of pain.

Maternal Factors That Influence the Severity of Erythroblastosis Fetalis. H. L. Teate Jr. Obst. & Gynec. 5:819-825 (June) 1955 [New York].

About 300 pregnant women were sensitized to Rh antigens. It was found that abortions, erythroblastotic infants, and transfusion of Rh-positive blood are strong immunizing agents. Abortions were found to be stronger immunizing agents than normal pregnancies but not as strong as erythroblastosis or Rh-positive transfusions. The mortality rate of liveborn erythroblastotic infants not treated with replacement transfusion whose mothers had a history of one or more of the strong immunizing agents varied between 31.8 and 39.1% depending on the agent. The untreated infants whose mothers had had only normal pregnancies had a mortality rate of 13.8%. With replacement transfusion the previous history made little difference. The rate of occurrence of fetal hydropic stillborn infants was only 3.6% when the previous maternal history was normal and 5.9% when abortions were included. With a history of previous erythroblastosis, the stillbirth rate was 26.1%; it was 21% when all the strong immunizing agents were included in one group. In spite of these findings, the author saw 45 mothers who had previously had affected infants and subsequently gave birth to Rh-positive infants who were less severely affected. The mothers who had antibody studies during pregnancy were divided into two groups according to height of titer. In group 1 in which the titer was under 1:32 there was an incidence of 13.9% of severely affected liveborn infants, with a general mortality rate of 8.9%. Infants were stillborn in 8.9% of the total pregnancies. In group 2, with titers higher than 1:32, 43.2% were severely affected liveborn infants and the mortality rate was 27.2%. Stillborn infants occurred in 22.1% of total pregnancies. The mortality was low in both groups if replacement transfusions were performed. Serial antibody studies are of greater value the earlier in pregnancy they are performed. Titers that are negative or very low and progress to a low, moderate, or high level usually indicate erythroblastosis of mild, moderate, or severe degree respectively. It is a bad prognostic sign if the high titer drops at or near term. When the titer does not rise to a high level, a normal Rh-positive or Rh-negative infant may be born. A low, moderate, or high titer early in pregnancy that remains fairly constant or diminishes gradually usually indicates a normal Rh-negative fetus. It is never justifiable to discourage another pregnancy for a sensitized mother regardless of maternal history or antibody titer, provided the mother is willing to take the risk of stillbirth. If the infant is liveborn, it has an excellent chance of survival and neurological normalcy if adequately and immediately treated.

PEDIATRICS

A Clinical Pathological Study of the Newborn Lung with Hyaline-Like Membranes. E. F. Latham, R. E. L. Nesbitt Jr. and G. W. Anderson. Bull. Johns Hopkins Hosp. 96:173-198 (May) 1955 [Baltimore].

The lungs of newborn infants dying in the early neonatal period are often found to contain an eosinophilic membrane with a hyaline-like appearance lining the dilated alveoli and air ducts, and this is often associated with atelectasis of the remaining alveoli. At Johns Hopkins Hospital, 480 neonatal deaths occurred among 26,213 live births in the weight group of 1,000 gm. and over. The lungs of 407 of the 480 infants were available for autopsy. Histologically 124 (30.5%) were found to have pulmonary hyaline-like membranes. A further analysis revealed an incidence of this lesion per 1,000 live births of 3.7 in the 1,000 to 2,499 gm. group and 0.99 in the 2,500 gm. and over group. The liveborn infants that weighed between 400 and 999 gm. were omitted from this investigation, but in a study of these infants 13 of 52 demonstrated hyaline-like membranes. The opinion that hyaline-like membranes are not found in the lungs of stillborn infants was supported by this study in which no such membrane was found in the examination of the lungs of 563 stillbirths. The hyaline-like membranes were graded according to thickness and distribution. The percentage of atelectasis was estimated by a comparison of the areas of lung tissue to the area of alveolar spaces. The cases were further subdivided according to the grade of hyaline-like membrane and the percentage of atelectasis. The total incidence of hyaline-like membrane is 4.7 per 1,000 live births (over 1,000 gm.) without significant atelectasis, but when combined with at least 70% atelectasis the incidence falls to 2.4. The cases of hyaline-like membrane were associated with a higher than average incidence of such factors as prematurity (6.9 times higher), multiple pregnancy, and delivery by cesarean section (27% of total cases). There was an increased incidence of hyaline-like membranes also in the lungs of infants of diabetic mothers, particularly in those delivered by cesarean section. The infants with pulmonary hyaline-like membranes lived an average of 30 hours, and an inverse proportion between length of life and extent of membrane was found. In 70% or more of the cases in which the authors considered hyaline-like membranes to be the sole cause of death, there was an associated pulmonary atelectasis. These cases represented nearly 30% of the total group with hyaline-like membrane, but only 8.6% of the entire group of neonatal deaths. The presence of major pathological changes outside the lung confuses the problem of classification. The importance of the finding of a hyaline-like membrane in the infant lung is attested by the fact that about 25% of the infants who died in this series had the membrane to some degree. The finding goes hand in hand with prematurity, and both may have a common cause.

Neonatal Convulsions. A Minkowski, S. S.-A. Dargassies and D. Samson. Rev. prat. 5:1553-1561 (May 21) 1955 (In French) [Paris, France].

In 19 cases of neonatal convulsions out of 67 observed over a five-year period, 7 babies died. The two worst prognostic signs were early onset and, especially, long duration of the convulsive state. Favorable signs were: predominance of signs of meningeal irritation (rigidity, tremor) over signs of central nervous disorder (staring, lack of Moro reflex, respiratory disorders); cherry red color of the cerebrospinal fluid; rapid improvement in the general condition after one or two lumbar punctures; and improvement in the neurological state in less than four days. When the state of suffering lasts more than 24 hours treatment is urgently required. This should consist of repeated lumbar puncture and the administration of massive doses of chloral and gardenal.

Celiac Disease: The Relative Importance of Wheat Gluten. C. A. C. Ross, A. C. Frazer, J. M. French and others. Lancet 1:1087-1091 (May 28) 1955 [London, England].

Until recently steatorrhea was recognized as one of the most constant findings of celiac disease, but the steatorrhea of celiac disease was not clearly differentiated until Andersen in 1938 isolated fibrocystic disease of the pancreas as a separate entity, and showed that the steatorrhea in fibrocystic disease resulted from deficiency of pancreatic lipase. Celiac disease was more fully explained when Dicke, Weijers, and van de Kamer demonstrated in 1950 that children with celiac disease recovered when wheat and rye flours were excluded from their diets. Subsequently it was shown that the gluten fraction of wheat and of rye contained the harmful substance and that the starch fraction was harmless to these children. The studies reported here aimed to determine what proportion of children with celiac disease respond to a diet free from wheat gluten (rye is not a common food in Britain), and what caused the disorder in those children who did respond to a gluten-free diet. Of 30 children with active celiac disease all but 2 responded to diets free from wheat gluten. The main diagnostic criterion was chronic steatorrhea with normal pancreatic function and the main therapeutic criterion was disappearance of the steatorrhea. As all the children had been ill for several months before treatment, their recovery on the diet is strong evidence in favor of the causal relationship of wheat gluten to their illness. More precise evidence of this relationship was obtained by the reappearance of steatorrhea on reintroduction of wheat gluten into the diet of 12 of these 28 children. In the children who recovered on a wheat gluten-free diet improvement in fat absorption coincided with improvement in the chylomicrograph, standard weight for age, hemoglobin level, and diminution in the dilatation of the small intestine, but not with any significant improvement in the glucose tolerance test. Of the two children who did not respond to the diet, one appeared to have a deficiency of bile salts and the other child showed fat intolerance. The authors suggest the term "gluten-induced celiac disease" for the disorder in those children who recover on diets free from wheat gluten.

Wheat Germ in the Treatment of Prematurely Born Infants. H. Mannkopf. Kinderärztl. Praxis 23:193-197 (May) 1955 (In German) [Leipzig, Germany].

Wheat germ, which is removed from wheat flour by modern methods of milling, contains, in addition to the B_2 group hormones, vitamin E, unsaturated fatty acid (vitamin F), amino acids, minerals such as calcium phosphate and magnesium phosphate, diastase, amylase, lipase, phosphatase, and tyrosinase. Its most important hormone, vitamin E, has a favorable influence on capillary resistance and capillary permeability. Prematurely born infants are supposedly especially susceptible to the lack of vitamin E. In 1953 the author undertook a systematic study of the effect of ground wheat germ on prematurely born infants. After the infants had been maintained for 30 days on fresh human milk, they were gradually (in increments of 50 gm.) put on a formula of acidified whole milk. This formula was prepared from a whole milk powder that had a fat content of 2.5% with 5% ordinary sugar and 2% of a Zea mays (Indian corn) preparation. A mountain ash juice was used for acidification. In infants in whom the efficacy of wheat germ was to be tested, half of the 2% Indian corn preparation, that is 1% of the formula, was replaced by ground wheat germ. A total of 142 prematurely born infants was studied, of whom 71 received the wheat germ addition and 71 did not. The wheat germ addition had no harmful effect, and it did increase the weight of the infants. While it had no noticeable effect on the resistance to infection or on anemia, it did seem to reduce the incidence of rickets in the prematurely born infant.

Fractures of the Extremities in the Newborn. E. T. Madsen. Acta obst. et gynec. scandinav. 34:41-74 (No. 1) 1955 (In English) [Stockholm, Sweden].

Of 786 fractures of the extremities in 105,119 newborn infants, 726 were fractures of the clavicle and 60 were fractures of the long bones. Fractures of the clavicle occur, as a rule, in cephalic deliveries, and they usually affect the anterior shoulder. Prognosis is excellent, and treatment is unnecessary in most patients. Of the 60 fractures of the long bones, 37 were fractures of the humerus, 20 of the femur, and 3 of the tibia and fibula. Fractures of the humerus and of the femur most frequently occur as a result of obstetric maneuvers, whereas fractures of the leg are, as a rule, caused by congenital disturbances of ossification. The typical lesion of the humerus in the newborn infant is a transverse fracture in the middle of the shaft with marked angulation but never more than 1 cm. of shortening. The typical lesion of the femur is an oblique fracture in the upper third of the shaft with marked angulation and occasional shortening of up to 3 cm. Results depend on early and adequate treatment with frequent roentgenologic control. Follow-up examination of 26 patients with fractures of long bones at birth showed that the original site of the fracture was practically always roentgenologically detectable even after 30 years. Fractures of the humerus have an excellent prognosis, and for their treatment the U-shaped Spitzy splint is recommended. Fractures of the shaft of the femur are preferably treated by traction with the aid of the Watson-Jones suspension frame or a small Thomas splint to avoid permanent shortening and angulation that may result when Credé's method is used. The first two methods secure immobilization of the fragments in adequate position and make possible breast feeding, easy transport, and easy nursing. Congenital fractures (fractures in utero and most fractures of the leg) have an unfavorable prognosis and their treatment must be carried out in the orthopedic department.

OPHTHALMOLOGY

Unilateral Exophthalmos Due to Orbitofrontal Cholesterol Granuloma. J. W. Hanbry and M. Rayport. Am. J. Surg. 89:1144-1162 (June) 1955 [New York].

In nine patients with orbitofrontal cholesterol granuloma, two cases were recent and not previously reported, five were taken from the literature, one was seen by one of the authors and reported previously, and one was restudied from the files of the Montreal Neurological Institute. All lesions were solitary and occurred in young or middle-aged men. There was a definite history of trauma in two patients. Unilateral exophthalmos and diplopia were the commonest symptoms. Forward, inferior, and medial displacement of the eye with restriction of upward gaze were the most constant findings. In six patients there was a visible or palpable abnormality of the lateral portion of one supraorbital ridge. There was radiographic evidence of an osteolytic lesion in the lateral portion of one supraorbital ridge with involvement of the adjacent frontal squama, orbital roof, and zygomatic process of the frontal bone in all eight patients in whom roentgenograms were obtained. All patients were operated on, and in each a cavity filled with a soft, yellowish-brown, amorphous, gritty substance was found in the bone. There was compression of the orbital fascia in each instance. No invasion was demonstrated through the orbital fascia or frontal dura. The microscopic appearance in all cases was that of a granuloma containing large numbers of cholesterol crystal clefts, foreign body giant cells, foam cells, histiocytes with eosinophilic cytoplasm, inflammatory cells, blood pigment, and collagenous connective tissue. Local excision resulted in prompt recovery, and there has been no evidence of recurrence. A conservative surgical approach with curettage is therefore recommended for these patients. The cause and pathogenesis of this disease remain unknown. The lesions may be related to the histiocytic granulomas of the Schüller-Christian type, but conclusive evidence is lacking.

The Status of Lenticular Opacities Caused by Atomic Radiation: Hiroshima and Nagasaki, Japan, 1951-1953. R. M. Sinskey. Am. J. Ophth. 39:285-293 (March) 1955 [Chicago].

The discovery in 1949 of radiation cataracts in American physicists induced the Atomic Bomb Casualty Commission to study ocular injuries in the survivors of the Hiroshima and Nagasaki bomb explosions. Slitlamp and ophthalmoscopic studies were made on survivors with previously diagnosed radiation cataracts. Definite diagnostic criteria having thus been established, larger numbers of survivors and nonexposed persons were examined. One group consisted of survivors of the nuclear explosion giving a history of 90 to 100% epilation, that is, scalp hair fell out one to three months after the explosion. This was believed to be the most heavily irradiated group. The control group was not in Hiroshima during or shortly after the bombing. This study of 3,700 exposed and nonexposed persons indicates that the human lens is extremely sensitive to nuclear radiations. Subcapsular plaques that previously were interpreted as normal were shown by statistical analysis to be significant effects of nuclear radiations. There is evidence that morphological characteristics of radiation cataracts may be confused readily with lenticular opacities of other origins that occur primarily in the postsubcapsular region axially. The incidence of these posterior subcapsular plaques can be correlated with age, epilation, shielding, and distance from ground zero. Observations over a four year period revealed that the posterior subcapsular opacities either increased slowly or not at all. The loss of vision has been negligible so far. Although in most persons the lenticular opacities are so insignificant as to be invisible with the ophthalmoscope, they are important in terms of dosimetry. Significant lental changes are present in survivors without any other known early or late evidence of radiation damage. With the conversion of atomic energy to power production, many workers will be exposed to nuclear radiations. It is important to recognize the earliest signs of radiation injury for the protection of the employees.

Deformities and Rh Incompatibilities. U. Bork, W. Marget and H.-H. Unger. Ärztl. Wchnschr. **10**:481-484 (May 27) 1955 (In German) [Berlin, Germany].

A concurrence of eye deformities with Rh factor incompatibilities was observed in five children in the course of one year. With one exception, the mothers of these children still had Rh antibodies in their blood; the exception was a mother in whom more than a year had elapsed since delivery. The routine search for Rh incompatibility in children with defective development of the eyes is regarded as chiefly responsible for the discovery of these cases in a relatively short time. The demonstration of antibodies often suggested that hitherto unexplained defects could be traced to the same cause. The authors feel that the close cooperation between pediatricians, serologists, and ophthalmologists was largely responsible for the clarification of the reported cases, in that it revealed otherwise more or less obscure changes that proved decisive in the diagnosis. The following defects were observed. One child had a coloboma of the optic nerve. A second one had atrophy of the optic nerve with bilateral juxtapapillary atrophy of the choroid, coloboma of the macula as well as "pepper-and-salt" fundus. A third one had microphthalmus, and the other two children had lamellar cataract, which in one of them was associated with optic atrophy. The anamneses, except in one of these children, disclosed no other symptoms of Rh incompatibility, a fact that suggests that the manifestations of the incompatibility must have been limited to certain embryonal periods. Nevertheless, the authors hope that a search will be made for Rh incompatibilities in similar cases.

THERAPEUTICS

Clinical Experiences with New Intestinal Antiseptic. N. Lo Duca and F. Irato. Sett. med. **43**:38-40 (Jan. 31) 1955 (In Italian) [Florence, Italy].

Siosteran, 5-7-dichlor-8-oxyquinaldine, was used to treat 12 infants, 2 to 8 months of age, 25 adults with enterocolitis, and 8 patients with intestinal amebiasis. One 0.1 gm. tablet of the preparation was given to the infants daily in divided doses for five days, and the adults received three to four such tablets daily for six days. All the patients tolerated the drug well, and the results were excellent. The diarrhea improved markedly in the infants as well as in the adults within 24 hours, and restoration to normal occurred in two to four days. Tests revealed no alterations in the liver and kidney function of these patients, and the blood findings were not altered.

Therapeutic Agents in Rheumatic Carditis: Comparative Effects of Acetylsalicylic Acid, Corticotropin, and Cortisone. B. L. Stolzer, H. B. Houser and E. J. Clark. A. M. A. Arch. Int. Med. **95**:677-688 (May) 1955 [Chicago].

Stolzer and his associates treated 52 patients with acetylsalicylic acid, 38 patients with cortisone, and 38 patients with corticotropin. The patients were airmen, who met the standard diagnostic criteria, and who exhibited signs of rheumatic activity when the treatment was begun. The majority of these young adult males were experiencing their first attack of acute rheumatic fever. Treatment was started early in the course of their illness, over 50% of the patients being treated in the first week. In those treated with acetylsalicylic acid the daily dose never exceeded 9 gm. (150 grains). The patients received the drug during the first two days every four hours in daily dose of 60 mg. per pound of body weight, thereafter every six hours in daily dose of 40 mg. per pound of body weight. The dose of cortisone was 300 mg. the first day, 200 mg. for the following five days, and 100 mg. from the 6th to the 21st day, and thereafter the dose was reduced first to 75 and then to 50 mg. daily to the end of the sixth week. Corticotropin was used in the form of ACTHAR in a daily dose of 120 mg. for the first four days, 100 mg. from the fifth to the seventh days, and thereafter the daily dose was reduced by 20 mg. every week, so that during the sixth week the daily dose was 20 mg. Each drug was given for six weeks, but if three weeks after the cessation of treatment any patient still met the established criteria for rheumatic activity, retreatment was instituted for four weeks, with the same drug and dosage schedule. All patients received 3 gm. of potassium chloride orally each day during treatment and a diet containing less than 2 gm. of sodium per day for the first four weeks. In order to eradicate streptococci and to prevent new streptococcal infections each patient received penicillin, after which they were given sulfadiazine (1.0 to 1.5 gm. per day). The patients were kept at bed rest for at least nine weeks and were then allowed a gradually increasing activity. No one drug employed exhibited marked advantages over the others in the treatment of the acute manifestations of rheumatic fever. The fewest patients with murmurs were in the cortisone treated group, 18%, in contrast to 34% in patients treated with either acetylsalicylic acid or corticotropin. It seemed that cortisone prevented the appearance of apical systolic murmurs and caused the disappearance of existing apical systolic murmurs during the treatment period to a greater degree than either acetylsalicylic acid or corticotropin. This difference during therapy was reflected in the 14th-month evaluation. The seemingly favorable effect of cortisone was also evident when aortic diastolic and apical middiastolic murmurs were considered, although the numbers were small. The differences observed among the three treatment groups do not allow a definite conclusion as to whether cortisone and corticotropin are superior to acetylsalicylic acid in the prevention of rheumatic valvular heart damage.

Nitrofurantoin: Clinical and Laboratory Evaluation. B. A. Waisbren and W. Crowley. A. M. A. Arch. Int. Med. **95**:653-661 (May) 1955 [Chicago].

Waisbren and Crowley report laboratory and clinical studies on nitrofurantoin, a derivative of the nitrofurans with the chemical formula N-(5-nitro-2-furfurylidene)-1-aminohydantoin. In vitro studies of the antibacterial activity of nitrofurantoin revealed that it has a wide antibacterial spectrum, is relatively bactericidal, and does not readily invoke resistant mutants. Nitrofurantoin was found particularly effective against Micrococcus pyogenes and Proteus but was ineffective against Pseudomonas aeruginosa. Sixty patients with infection of the urinary tract were treated with nitrofurantoin. The results were satisfactory in 27 patients, unsatisfactory in 12, and indeterminate in 21. Fourteen of the 27 patients in whom treatment was effective had received prior unsuccessful therapy with antibiotics. These results were equal to or superior to those that would have been obtained with any other single antimicrobial agent. Nine patients had varying degrees of nausea and vomiting due to the nitrofurantoin, but no diarrhea or evidence of toxicity was found.

Treatment of Polyarthritis Chronica with Nitrogen-Mustard (Erasol). G. Retbøll, T. Egemose, and J. E. Holst. Acta med. scandinav. **151**:289-294 (No. 4) 1955 (In English) [Stockholm, Sweden].

Intravenous injections of nitrogen mustard (Erasol) were given to 12 patients between the ages of 37 and 60 years with chronic polyarthritis at the Town and County Hospital in

Roskilde, Denmark. The daily dose of the drug was 0.1 mg. per kilogram of body weight, and it was given as a rule for four consecutive days, and in one case for six days. The condition of all the patients improved in the course of the treatment, though in most of them only slightly. The improvement was of short duration. Most patients became sick and vomited a few hours after administration of Erasol although it was never considered necessary to discontinue the treatment, except in one patient for one day. Erasol cannot be recommended for use on a large scale, but only for giving brief relief to patients in whom other methods of treatment have failed.

Myleran (GT 41) in the Treatment of Leukemia. A. Videbæk. Acta med. scandinav. **151:**295-306 (No. 4) 1955 (In English) [Stockholm, Sweden].

Six adult patients and one 2-year-old boy with chronic myelocytic leukemia, one woman with myelosclerosis, one woman with acute myelocytic leukemia, and one man with subacute monocytic leukemia were treated with 1,4-dimethanesulfonyloxybutane (Myleran). The drug is available in tablets of 2 mg., and the initial dose given varied from 6 to 12 mg. daily in adult patients, while the child received 2 to 4 mg. of the drug daily. The drug was withdrawn or the dose reduced when the white blood cell count approached normal. Six patients received two courses of treatment. The follow-up period ranged from 2 to 16 months, averaging 8 months. The six adult patients with chronic myelocytic leukemia responded satisfactorily to the treatment and had remissions of two to eight months' duration. Normal white blood cell counts were obtained within one month on the average, but in one patient who received only 6 mg. of the drug daily, treatment had been continued for two to three months. The remissions were as good as those obtained by previous roentgenotherapy. The child with myelocytic leukemia had severe anemia during the first course of Myleran, but this patient had shown signs of hemolysis also before the treatment. He received two courses of Myleran and during both courses a marked decrease in leukocytes was observed. During the second course thrombocytopenia was also noted. The patient with myelosclerosis received 404 mg. of the drug in the course of 58 days; the treatment then had to be discontinued because of incipient pancytopenia. Fifteen months after discontinuation of the treatment the patient was still in a state of satisfactory remission and the originally enlarged spleen was not palpable. The drug was of little therapeutic value in the patients with acute myelocytic leukemia and subacute monocytic leukemia. Myleran is easy to administer and may be given even to outpatients, but the patients must be under careful hematological control. No immediate undesirable side-effects were observed.

Chemotherapy of Bacterial Infections Refractory to the Common Antibiotics. M. S. Bryer. Am. J. Med. **18:**782-791 (May) 1955 [New York].

Since the introduction and widespread use of antibiotics, organisms formerly considered semisaprophytes and minor pathogenic agents, such as Proteus vulgaris, Pseudomonas aeruginosa, coli-aerogenes, Micrococcus (Staphylococcus) aureus, and the enterococcus, have emerged as common causative agents of refractory infections. As the result of an extensive review of the literature including 126 papers, Bryer states that with proper precautions and careful observation, more toxic antibiotics such as polymyxin (Aerosporin), neomycin, and bacitracin may be successfully used in the treatment of these infections. Polymyxin is strongly bactericidal, and its activity is largely confined to gram-negative bacilli. It is effective against these organisms, with the striking exception of Proteus vulgaris, in extremely low concentration. Pronounced therapeutic activity with only minor toxic manifestations can be obtained with total daily intramuscular doses of 2 to 5 mg. of polymyxin per kilogram of body weight. In low concentration neomycin is markedly bactericidal for gram-negative organisms, and at slightly higher levels it is active against many gram-positive bacteria. Renal and also auditory reactions must be observed. When a total daily dose of 10 mg. per kilogram, or about 2,000 units per kilogram, is divided into four equal injections and administered intramuscularly in 1 or 2% procaine solution at six-hour intervals no difficulty is observed. Bacitracin is markedly bactericidal for gram-positive organisms. Serious toxic manifestations are uncommon when bacitracin dissolved in procaine is injected intramuscularly in a daily dose of 1,000 units per kilogram. This total daily dose is best given at six-hour intervals. In addition, erythromycin (Ilotycin and Erythrocin), carbomycin (Magnamycin), and nitrofurantoin (Furadantin) are more recent chemotherapeutic agents that are of some assistance in combating organisms resistant to the older antibiotics. Both erythromycin and carbomycin are of low toxicity and are active against gram-positive bacteria, rickettsias, and certain of the large viruses. Both antibiotics are usually well tolerated in total daily oral doses of 20 to 40 mg. per kilogram administered at four-hour or six-hour intervals. Nitrofurantoin is active against both gram-positive and gram-negative bacteria. The blood concentrations achieved with the usual daily dose of 5 to 10 mg. per kilogram are extremely low and limit this agent to the treatment of infections of the genitourinary tract since nitrofurantoin is excreted in high concentration in the urine. The successful treatment of a refractory bacterial infection depends on the early and proper evaluation of the diagnosis and the host factors involved as well as consideration of the chemotherapeutic and bacterial agents. The answer to eradication of these infections will most frequently be found in sound clinical judgment, application of long-established principles of general medical and surgical therapy, and in carefully standardized and controlled laboratory sensitivity determinations.

Experiences with Ossopan in Orthopedic Disorders. O. Popp. Helvet. chir. acta **22:**140-152 (May) 1955 (In German) [Basel, Switzerland].

Ossopan, a complete bone preparation made from crude long bones of young healthy animals, freed from fat, with epiphyses and red bone marrow, was given a therapeutic trial in 47 patients with various orthopedic disorders at the Orthopedic Hospital in Vienna, Austria. One tablet of the drug was given six times daily, and this dose was tolerated well even by small children. No undesirable side-effects were observed. The results obtained proved that Ossopan is a valuable aid in the treatment of bone defects. Patients with bone grafts, delayed healing of fractures, formation of pseudarthrosis, and transformation zones of bone, all were benefited from the administration of this drug. It stimulated recalcification in tuberculous processes as well as in Sudeck's syndrome. Ossopan also had a favorable effect on senile osteoporosis. Ossopan favors the absorption of calcium and its retention in the organism and in addition seems to exert an effect on the new growth of bone and on bone restitution.

The Treatment of Shigellosis: I. Synergistic Effect of Antibiotics on Shigella. H. Seneca and E. Bergendahl. Am. J. Digest. Dis. **22:**131-139 (May) 1955 [Fort Wayne, Ind.].

The effect of antibiotics on Flexner, Boyd, and Sonne strains of Shigella paradysenteriae using the tube dilution method, and the synergistic effect of antibiotics on Shigella paradysenteriae were studied. Results showed that neomycin combined with polymyxin (Aerosporin) in 1:10 ratio potentiates the inhibitory effect of neomycin and polymyxin on S. paradysenteriae 5 to 30-fold and 25 to 70-fold respectively. Neomycin combined with streptomycin in 1:10 ratio potentiates the inhibitory effect of neomycin and streptomycin on Shigella 1.5 to 2.5-fold and 2.5 to 3-fold respectively. Neomycin combined with tetracycline (Achromycin) or oxytetracycline (Terramycin) in 1:10 ratio potentiates the inhibitory effect of neomycin on Shigella 1.5 to 2.5-fold and 2.5 to 3-fold. Neomycin combined with carbomycin (Magnamycin) in 1:1,250 ratio enhances the inhibitory effect of neomycin 1.5 to 2.5-fold, and of carbomycin 0.5 to 8-fold, and in the same ratio, neomycin combined with bacitracin enhances the effect of neomycin 2.5 to 3-fold, and the effect of bacitracin one-fold to two-fold. Neomycin combined with viomycin in 1:10 ratio depresses the inhibitory effect of both antibiotics. In the treatment of shigellosis or other types of localized infections of the intestinal tract, the ideal therapeutic agent should have specific action on the causative agent, be nontoxic, permeate the intestinal wall adequately, and not be absorbed into the systemic circulation. Neomycin combined with polymyxin fulfills practically all of these requirements.

New Treatment of Barbiturate Intoxication. A. Shulman, F. H. Shaw, N. M. Cass and H. M. Whyte. Brit. M. J. 1:1238-1244 (May 21) 1955 [London, England].

The use of two new substances in the treatment of barbiturate poisoning in 41 patients is reported on. The agents are $\beta\beta$-methylethylglutarimide (NP13) and 2:4-diamino-5-phenylthiazole hydrobromide or hydrochloride (DAPT). In the 41 patients with pure barbiturate intoxication, of whom 9 were seriously ill, one death occurred. There was strong evidence that it was not caused by treatment, and the authors believe that their method warrants large-scale clinical trial. The merit of the method lies in the fact that the more active agent, NP13, unlike the central analeptics in current use, appears to exert a direct antagonism to the offending barbiturate and will readily restore the patient from a deep coma to a state of light anesthesia—the "safe state"—from which spontaneous recovery to full consciousness usually occurs within eight hours. This removes the need for strict and prolonged medical and nursing care, and virtually eliminates the risk of complications. DAPT, itself a weak barbiturate antagonist, is, however, a good synergist to NP13 as well as an excellent respiratory stimulant. It greatly reduces the risk of the toxic manifestations that sometimes occur when NP13 is given rapidly and in large doses. These substances may provide an effective means of controlling anesthesia induced by barbiturates both by permitting a rapid recovery to the conscious state when desired and by counteracting any emergency such as laryngeal spasm. DAPT may also be of value as a nonspecific respiratory stimulant.

A New, Mild Sedative-Hypnotic, A Piperidine Derivative (Noludar). O. Brandman, J. Coniaris and H. E. Keller. J. M. Soc. New Jersey 52:246-253 (May) 1955 [Trenton, N. J.].

Noludar (3,3-diethyl-2,4-dioxopiperidine or Ro 1-6463) is a new nonalkaloidal central nervous system depressant that is not a barbiturate. A series of 500 patients was given excessive doses nightly for four weeks. After a rest period of two weeks, the patients were reexposed to high doses of the drug for one week. Frequent hemograms failed to reveal any toxic hematological findings. Noludar was given for night sedation to 1,015 patients; 1,000 of these received 250 mg. doses for three consecutive nights. The resulting average sleep induction period was 29 minutes and the average duration of sleep seven hours. Side-effects such as drowsiness, vertigo, and nausea were experienced by only 13 patients; 979 patients rated the hypnotic effect of Noludar as at least equal to barbiturates they had previously received. Noludar was administered for daytime sedation to 510 patients who were given 50 mg. doses three times a day for four weeks. This plan provided sedation comparable to that obtained from 16 mg. of phenobarbital three times a day. There was no drowsiness or oversedation from Noludar, and all patients were pleased with its action. The authors conclude that Noludar is an effective sedative-hypnotic of fairly prompt onset and short duration of action that, in therapeutic doses, is distinguished by excellent tolerability and meets with wide patient acceptance.

Combined Nitrogen Mustard and Urethane Therapy of Chronic Granulocytic Leukemia. E. Keibl. Wien. klin. Wchnschr. 67:356-361 (May 20) 1955 (In German) [Vienna, Austria].

Seven patients between the ages of 27 and 69 years with chronic granulocytic leukemia were given daily intravenous injections of 1.25 mg. of nitrogen mustard and of 1.5 gm. of ethyl urethane, i. e., half of the usual daily doses of both drugs. Treatment was continued until leukocyte values of about 20,000 per cubic millimeter were reached, and that occurred usually at the end of the second week. Marked maturation in the peripheral blood picture and notable diminution in the size of the liver and spleen occurred simultaneously. Except for occasional nausea three to four hours after the injection, the treatment was well tolerated; it was therefore possible to give the patients, after their discharge from the hospital, one to two injections per week if necessary. The duration of the prompt remission that occurred in all of the author's patients varied from several months to one and a half years. In the third year of their disease, three of the patients, who had been treated exclusively with nitrogen mustard combined with urethane, were cautiously treated with small doses of x-ray. An unexpectedly prompt drop in the leukocyte count with remission resulted within one week. A change of therapy makes daily blood counts, or counts at least every second day, imperative. The metabolism of the leukocytes was similar to that after treatment with urethane alone, but instead of occurring only on the 20th day after the institution of treatment, it occurred on the 4th day. The simultaneous decrease of respiration and increase of glycolysis that occurred toward the end of the combined treatment can be interpreted as a sign of peripheral cell damage, a behavior similar to that after treatment with nitrogen mustard. The combined treatment with nitrogen mustard and urethane seems to potentiate the effect of both drugs at the beginning of the treatment, and a certain balance in the late phase of the treatment may prevent the risk of late damage caused by the administration of larger doses of urethane.

Oral Administration of Penicillin: A Comparative Study of Benzathine Penicillin, Procaine Penicillin and Potassium Penicillin. S. E. Budolfsen, S. E. J. Hansen and E. Rud. Acta pharmacol. et toxicol. 11:49-54 (No. 1) 1955 (In English) [Copenhagen, Denmark].

A comparative study was made of the penicillin concentrations obtained in the serum of bedridden patients between the ages of 18 and 70 years after oral administration of 600,000 international units of potassium penicillin, procaine penicillin, or benzathine penicillin. Results showed that potassium penicillin is absorbed more rapidly, gives a higher concentration, and causes a more prolonged penicillemia than benzathine penicillin or procaine penicillin. The authors' studies suggest that oral administration of 600,000 I.U. of potassium penicillin gives a peak concentration slightly lower than that obtained by intramuscular injection of 200,000 I.U. with the penicillemia persisting for a slightly longer period.

Seasonal Variations in Sensitivity of Microorganisms to Antibiotics. B. J. McMahon. South. M. J. 48:480-485 (May) 1955 [Birmingham, Ala.].

The appreciation of the importance of the specificity of antibiotics for infections has prompted the elaboration and use of methods to determine such specificity. A survey was conducted to ascertain whether bacterial sensitivity could be accurately determined in a shorter time than the usual 48 to 72 hour period required by present laboratory methods. Likewise, it was intended to determine whether there may be a seasonal variation in the sensitivity of micro-organisms to antibiotics. The degree of sensitivity of micro-organisms cultured from the ears, nose, and throats of 230 patients with and without infections to chlortetracycline, chloramphenicol, oxytetracycline, and penicillin was determined over a 12 month period. Using the disk method to determine the sensitivity, a comparison was made between the 72 hour technique and an experimental 24 hour technique. The experimental 24 hour technique was 80.4% as accurate as the 72 hour methods. This is an advantage to the patient in that 48 hours is saved toward the more accurate administration of the antibiotic specific to his infection. The sensitivity tests showed a definite trend toward a greater resistance of the micro-organisms to the antibiotics during the months of August, September, and October.

PATHOLOGY

Cases of Disseminated Lupus Erythematosus Diagnosed as Idiopathic Thrombocytopaenic Purpura. S. L. Eversole Jr. Bull. Johns Hopkins Hosp. 96:210-222 (May) 1955 [Baltimore].

Thrombocytopenia and purpura may be the presenting or dominant symptom of disseminated lupus erythematosus, leading to the erroneous diagnosis of idiopathic thrombocytopenic purpura. Other symptoms of disseminated lupus erythematosus may not be recognized for months or even years following the onset of the purpura. The author studied six cases of thrombocytopenic purpura in which the relationship to disseminated lupus erythematosus was established only at autopsy or on finding the characteristic histological lesion in the spleen removed at operation for what was thought to be the idiopathic type of thrombocytopenic purpura. These cases demonstrate the importance of considering disseminated lupus erythematosus in all patients with thrombocytopenic purpura. The pathological lesion in the spleen that, when well marked, is generally regarded as pathognomonic of disseminated lupus erythematosus, is the "onion peel" fibrosis around arteries, particularly the small arteries, in the Malpighian bodies. The presence of disseminated lupus does not necessarily contraindicate splenectomy. Indeed, the thrombocytopenia and purpura may be alleviated, as was the case in five of the six patients presented in this paper.

Rigidity of Thorax and Myocardosis. W. Selberg. Deutsche med. Wchnschr. 80:749-752 (May 13) 1955 (In German) [Stuttgart, Germany].

Of 1,800 autopsies performed at the pathological institute of the Barmbek General Hospital in Hamburg, Germany, in the course of 18 months, "paramyloidosis" of the heart was observed in 20 cases of senile systemic disease of the thorax. The series included 14 men and 6 women between the ages of 72 and 92 years and with an average age of 84 years at the time of their deaths. Complete systemic disease of the senile thorax consists in its terminal stages of calcification and ossification of the bronchi, trachea, larynx, and costal cartilage; severe spondylosis deformans of the thoracic and cervical vertebral column with senile kyphosis; marked chronic pulmonary emphysema with bronchiectasis; formation of cartilaginous and bony spicules in the pleura; hypertrophy of the right side of the heart; pulmonary sclerosis; and muscular hypertrophy of the esophagus, pyloric antrum, and pylorus. The incidence of this complete systemic disease of the senile thorax increases with far advanced age and in the author's cases it was observed to be associated with the occurrence in the cardiac interstices of basophilic edema fluid rich in protein. Although this type of edema may also be observed frequently in young and middle-aged persons with rigidity of the thorax, it is most marked in old people with senile rigidity of the thorax. Homogeneous focal deposits of proteins in the endocardium and myocardium, particularly of the right side of the heart, were found in 60% of the old people with rigidity of the thorax. Although these albuminous deposits have a certain similarity to genuine amyloid on staining, they can be distinguished from it by the almost complete absence of metachromasia with methyl violet. There is also a topographic difference since the genuine amyloid, as a rule, is limited to the vascular apparatus and may be found in the heart in generalized forms only. Destruction of the enclosed muscle fibers was observed in all the larger foci of the author's cases. The metabolic process and the capacity for contraction of the muscle cells was thus made difficult. The fact that these changes were limited to old people suggests that from an etiological point of view one has to deal primarily with old-age changes of the mesenchymal metabolism. The rigidity of the thorax is a manifestation of the basic senile metabolic disturbance, but not a cause of the "paramyloidosis" of the heart.

Effect of Corticoids upon the Development and Toxicity of Transplantable Croton-Pouch Tumors. H. Selye. Endocrinology 56:516-522 (May) 1955 [Springfield, Ill.].

The growth and systemic toxicity of transplanted "croton-pouch tumor No. 2," a highly malignant fibrochondro-osteosarcoma that had first been induced in croton-oil treated animals, was examined in intact and in adrenalectomized rats treated with hydrocortisone, desoxycorticosterone acetate, or both these steroids. Using the "neoplastic granuloma pouch technique," in which tumor-tissue suspensions are introduced into regular, symmetrical subcutaneous air sacs, it was found that hydrocortisone greatly inhibits both the growth and the exudate-forming ability of croton-pouch sarcomas, but only in the adrenalectomized animals, i. e., in the absence of adrenal tissue. The antihydrocortisone action of the living adrenals could be duplicated in the adrenalectomized animals by simultaneous treatment with hydrocortisone and desoxycorticosterone acetate. These findings, as well as the effect of hydrocortisone on the body weight and death rate of these tumor-bearing rats, suggest that desoxycorticosterone acetate imitates the hydrocortisone-antagonizing effect of intact adrenal tissue in many respects.

Demonstration of Role of Irritating Factors and of Trauma in Elective Localization of Antibodies in Shock Organs. B. N. Halpern, G. Biozzi and B. Benacerraf. Acta allergol. 8:181-188 (No. 3) 1955 (In French) [Copenhagen, Denmark].

A series of experiments was performed on guinea pigs to show that contingent irritative factors (occasional irritation, repeated trauma, local infections, or occupational lesions) can influence the preferential localization of antibodies in a tissue. The intradermal injection of a minimal dose of histamine (0.5 to 3 gammas), traumatization by pinching of the skin or the application of heat, or injection of distilled water will cause local accumulation and preferential fixation of antibodies two hours after the injection of antibodies, while it takes 48 hours to produce the same phenomena in nontraumatized areas. Another experiment consisted of subjecting animals that had been injected with antibodies to inhalations of various irritants, such as aerosols of histamine or acetic acid, ammonia vapors, and hot air. The animals were then subjected, from 1 to 24 hours later, to inhalation or intravenous injection of ovalbumin, whereupon violent bronchial spasm occurred, sometimes strong enough to cause death. Control animals given the same amount of allergen but not having been traumatized showed no signs of bronchospasm, even 24 hours after exposure. The following explanation of the pathological mechanism of these phenomena is offered. Circulating antibodies are fixed in high titer in a region that has undergone trauma of some kind. When they come in contact with the antigen, there is local liberation of histamine that, in turn, causes a new and intense fixation of antibodies. This would explain the localization and elective choice of the shock organ.

The Importance of Microscopic Granulomas (Pseudotubercles) in the Diagnosis of Manson's Schistosomiasis. O. F. de Gouveia and W. D. Beamer. Gastroenterology 28:634-641 (April) 1955 [Baltimore].

One hundred sixty-five biopsies of the rectal mucosa were made in 62 patients with gastrointestinal complaints, selected only because of their prior residence in Puerto Rico, where intestinal schistosomiasis is highly endemic. A diagnosis of intestinal schistosomiasis was made in 23 of the 62 patients with the aid of the biopsies that were positive for Schistosoma mansoni. The biopsies of 13 of the 23 patients showed microscopic granulomas or typical schistosomal pseudotubercles, consisting of a zone of lymphocytes, eosinophils, monocytes and some epitheloid and giant cells, surrounded by a layer of concentrically disposed fibroblasts. Four of these 13 patients had granulomas alone, containing scarcely recognizable portions of ova of S. mansoni in some. The remaining nine showed in addition ova without fibroblastic response. Biopsy of the rectal mucosa is an efficient means of determining at one examination whether the patient has been infected with S. mansoni. The presence of the typical pseudotubercle, the schistosomal granuloma with identifiable ova, is sufficient for diagnosis. When readily recognizable ova are not present, the finding of a granuloma should cause suspicion and encourage further search for diagnostic material although activity of the disease can be ascertained only on finding viable ova.

In Vitro Studies on the Combination of Penicillin and Streptomycin. O. Kylin and E. -U. Wall. Acta med. scandinav. 151:281-288 (No. 4) 1955 (In English) [Stockholm, Sweden].

Tests of sensitivity to a combination of penicillin and streptomycin were carried out with a medium consisting of peptone-free blood agar for Micrococcus (Staphylococcus) aureus, Micrococcus albus, enterococcus, Escherichia coli, Klebsiella aerobacter, other coliform bacteria, Proteus, and Pseudomonas pyocyanea. The strains tested included 245 isolated from infections of the urinary tract, 489 from infections of the upper respiratory tract, and 276 isolated from ear infections. The effect of the combined antibiotics on these bacterial strains also was compared to that of the so-called broad spectrum antibiotics, chlortetracycline, chloramphenicol, and oxytetracycline. On the whole, the results of the sensitivity tests confirmed the general observation that the combination of penicillin and streptomycin may have a synergistic or indifferent effect against certain strains, but that it never produces an antagonistic effect. Inhibition of bacterial growth by penicillin combined with streptomycin thus was generally observed at a concentration much lower than that necessary for inhibition by the most effective of the two components alone. A synergistic effect was statistically demonstrable in less than half of the total number of strains tested. Nevertheless, it was concluded that in vitro the combination is to be preferred both to either of the antibiotics alone and to the broad spectrum antibiotics tested. The combination of penicillin and streptomycin should be of great value both as a therapeutic agent for infections of unknown cause and as a means of decreasing the dose of streptomycin in cases of infections particularly sensitive to streptomycin but resistant to penicillin. In such cases it may be possible to obtain an increase in the therapeutic range, thereby decreasing the risk of undesirable side-effects from streptomycin. The risk of development of resistant strains may also be lower with the combination than with either of these antibiotics alone. Compared with the concentrations of penicillin combined with streptomycin necessary for inhibition, the broad spectrum antibiotics on the whole showed a much lower efficacy. In most cases the differences in concentration were great, in some even up to 10 times. Only against Escherichia coli and Enterococci did the broad spectrum antibiotics give relatively better results.

RADIOLOGY

Experiences with the Use of Radioactive Cobalt in the Form of Plastobalt for Irradiation Treatment of Malignant Tumors. H. Lehrner and L. Psenner. Wien. klin. Wchnschr. 67:373-374 (May 27) 1955 (In German) [Vienna, Austria].

Plastobalt, a preparation of radioactive cobalt in a plastic material adjustable to the size and form of the malignant tumor to be treated, was used at the Central Roentgen Institute of the University of Vienna for surface therapy of carcinoma of the pinna in four patients, of the lip in one patient, and of the penis in one patient. Plastobalt was used for intracavitary treatment of tumors of the upper jaw in four patients and of carcinoma of the mastoid process in one patient. It was also used for irradiation treatment of a movable carcinoma of the vocal cord after operative removal of the ala of the thyroid cartilage. In the patient with carcinoma of the lower lip, inner and outer Plastobalt plates were applied. Irradiation was carried out for 60 hours in the course of 10 days; 6,000 r were administered to the outer skin and 8,000 r to the mucosa. The tumor disappeared completely, and there was no recurrence after one year. The four patients with carcinoma of the pinna received a surface dose of 5,500 to 6,500 r. All were free of symptoms one year after the treatment. Because of the favorable conditions of absorption of the hard gamma rays in the cartilage, there is much less risk of necrosis in the pinna with this type of irradiation than with short-distance roentgen irradiation. The patient with carcinoma of the penis received a dose of 4,800 r in the course of 11 days. Two years later there was no local recurrence of the carcinoma, but an inoperable lymph node infiltration was detected 16 months after the treatment. Of the four patients with tumors of the upper jaw, two were given immediate postoperative irradiation treatment and two received irradiation treatment for late recurrences at the posterior wall of the resection cavity; 5,600 to 7,100 r were applied to the surface of the wall of the resection cavity within four to five days. Of the two patients who were given immediate postoperative treatment, one had no recurrence two years later, and the other could not be followed up. Of the two patients with late recurrences, one died of intercurrent disease and the other had been observed for only three months. The patient with carcinoma of the mastoid had no recurrence after 18 months. The patient with carcinoma of the vocal cord received 5,200 r within 120 hours. After six months there were no clinical or microscopic signs of recurrence. Although Plastobalt has been used for only about two years, the authors believe that it has already shown itself to be a gamma emitter characterized by simplicity in technical handling, many-sided applicability, and a special suitability for the treatment of surface lesions.

Follow-Up Study of 100 Cases of Carcinoma of the Prostate Treated with Radioactive Gold. H. D. Kerr, R. H. Flocks, H. B. Elkins and others. Radiology 64:637-641 (May) 1955 [Syracuse, N. Y.].

The group 2 classification of prostatic cancer is applied to moderately advanced carcinoma in which local extension has made radical surgery of little use and in which distant metastases could not be demonstrated. One hundred patients with group 2 prostatic carcinoma were treated by interstitial radiation with radioactive gold, Au^{198}, that was inserted through a retropubic incision. They were followed for 15 to 27 months and were studied again one year later. Fifty-two additional patients were followed for a minimum of one year and a maximum of two years. A study of these patients indicates that rectal complications can be eliminated by careful use of the radioactive material, with only one significant complication remaining, i. e., calculus formation in the sloughing tissue. It is practically impossible to sterilize any except the smallest of neoplasms with radioactive material alone. Consequently the authors resorted to surgical removal of the tumor before or after interstitial injection of the Au^{198}. The time and method of surgical removal and of additional injections must be individualized for each patient. Subsequent perineal injections must be given for residual tumors. Of the first 100 patients followed for 24 to 39 months on June 1, 1954, 46 were alive, 18 with disease and 28 without disease; 54 were dead and of these at least 13 died of causes other than carcinoma. Since all of these patients would eventually die of cancer if treated palliatively, it seems worth while to continue this method in an effort to save some.

Comparative Studies of Discography and Myelography. J. Wolkin, M. D. Sachs and G. H. Hoke. Radiology 64:704-713 (May) 1955 [Syracuse, N. Y.].

The diagnosis of herniation or protrusion of an intervertebral disk can usually be made on the basis of the history and a careful examination. Myelography has been used extensively in patients in whom the clinical findings are inconclusive, but in the last decade Lindblom and others have emphasized that herniation of an intervertebral disk can be diagnosed by a direct puncture of the disk with the injection of 35% iodopyracet. They are of the opinion that this diagnostic method is more accurate and more rapid than myelography, as well as less hazardous to the patient. In an effort to verify this conclusion, both disk punctures and ethyl iodophenylundecylate myelography were performed in 18 patients. In nine others, discography alone was performed. The 27 patients had clear-cut clinical evidence of herniated disk, and in most neither myelography nor discography was considered necessary for the diagnosis. In 11 of the 18 patients subjected to discography and myelography, both procedures were accurate. Considered alone, myelography was completely accurate in 9 of 18 patients, partly accurate in 3, falsely negative in 4, falsely positive in one, and unsatisfactory in one. Discography alone was completely accurate in 18 of 27 patients, partly accurate in 7, falsely positive in one, and unsatisfactory in one. There were no false negative discograms. These results show that the accuracy of discography is superior to that of myelography. A normal discogram offers strong evidence against the diagnosis of a herniated lumbar disk. Unsuspected multiple herniations are seen more often during discography. Reduplication of radicular pain during the disk injection may further support the diagnosis of a herniated disk. Discography is a direct, apparently safe, relatively accurate, and rapid adjunctive procedure for the diagnosis of herniated lumbar intervertebral disks.

Hypaque, a New Urographic Contrast Medium. J. C. Root and W. C. Strittmatter. Am. J. Roentgenol. **73**:768-770 (May) 1955 [Springfield, Ill.].

Sodium 3, 5 diacetamido-2, 4, 6-triiodobenzoate (Hypaque), a new urographic contrast medium, was administered to 187 men and 163 women, ranging in weight from 97 to 280 lb. (44 to 127 kg.). All 350 patients were ambulatory, but no attempt at other selection was made. Each patient received 25 cc. of Hypaque given intravenously, usually in the antecubital vein. The length of time taken for the injection varied from one to three minutes. Postinjection reactions such as nausea, bad taste, vomiting, dizziness, warmth, flushing, hives, and moderate pain at the site of the injection occurred in 34 patients (9.7%), a significantly lower incidence than that reported when other contrast mediums were used. The incidence of reactions to Hypaque was nearly three times higher in the 20 patients with a history of previous allergies than it was in the remaining patients. The urograms were rated on the basis of diagnostic quality according to the criteria devised by Hoppe. Visualization of the urinary tract was excellent in 152 patients, good in 165, fair in 24, and poor in 9. In general, the "pyelogram-like" contrast was striking. Thus the value of Hypaque as a urographic contrast medium is twofold: it makes possible excellent visualization of the urinary tract, and it diminishes the number of postinjection reactions.

Quantity of Radiation Received by the Reproductive Organs of Patients During Routine Diagnostic X-Ray Examinations. R. W. Standord and J. Vance. Brit. J. Radiol. **28**:266-273 (May) 1955 [London, England].

Radiation can reach the reproductive organs either from the direct beam during investigations of the pelvic region or by scatter during investigations of other parts of the body. In men it can be measured directly by placing a suitable instrument in contact with the scrotum during the radiographic examination. In women the quantity can only be deduced from measurements made on the skin, and the determination of factors to convert these into ovarian doses becomes the primary problem. The surface point selected for women was on the anterior abdominal wall 1 in. medial to and 1.5 in. below the anterosuperior iliac spine. One of two Perspex ionization chambers, which had volumes of 10 and 1 ml. respectively, was affixed to the patient at this point during each routine radiographical investigation. Factors for converting surface into ovarian doses were determined on cadavers and models. The average quantities of radiation in milliroentgens received per film, as measured directly for men and deduced for women were based on measurements made on 1,500 patients. The records of about 9,000 patients were analyzed with regard to sex, age and type of examination. Since the authors were interested chiefly in possible genetic effects of irradiation, they considered only those age groups concerned with the highest birth rates. The values finally obtained for the average quantities of radiation reaching the reproductive organs per patient per examination are of the order of 35 milliroentgens for men and 60 for women. Regions such as the skull, the chest, and the extremities, which account for about 80% of all x-ray examinations, contribute only 1% to the average amount of radiation received by the reproductive organs; whereas examinations of the pelvic region contribute 60 to 70% of this radiation but only 2 to 4% of the examinations. It is these, therefore, that carry the greatest potential danger. Whether the levels of radiation reported in this paper are genetically significant must be decided by geneticists. If the quantities should be reduced, this can be done most readily by using the smallest possible fields in all examinations of the abdomen and pelvis and by reducing the numbers of examinations in these regions. This approach is considered likely to be more successful than any technical one such as the development of high kilovoltage radiography.

Thorotrast Spleen. E. Samuel. Brit. J. Radiol. **28**:204-205 (April) 1955 [London, England].

Thorium dioxide sol (Thorotrast) when injected into the blood am for diagnostic purposes is taken up by the reticuloendo- system and is slowly excreted by the kidneys. Samuel two cases of Thorotrast spleen. Although the roentgenologic appearance of Thorotrast in the spleen is quite distinct, when it is seen for the first time it may be a source of confusion. This is especially so as some patients, who show such deposits, may be unaware of the injection of Thorotrast. In both cases a cerebral angiogram using Thorotrast as a contrast medium had been performed under general anesthesia and the patient was consequently unaware of the injection. The symptoms presented by both patients did not appear to be connected with the Thorotrast spleen. Roentgenologically the Thorotrast spleen is characterized by a generalized increase in density of the splenic shadow unassociated with any enlargement of the spleen. The increase in splenic density has a fine mottled appearance, and the whole spleen has a granular appearance. There is no increase in the density of the splenic capsule. There is usually an enlargement and some increase in density of the liver shadow although this may not be as marked as that in the spleen. Conditions that have to be differentiated radiologically are: perisplenic calcification, miliary calcification, and calcification in a splenic cyst.

Acute Renal Failure Following Angiography: Especially the Risk of Repeated Examination, Revealed by Eight Cases (Two Deaths). N. Alwall, S. Johnsson, A. Tornberg and L. Werkö. Acta chir. scandinav. **109**:11-19 (No. 1) 1955 (In English) [Stockholm, Sweden].

In a series of eight patients with renal injury following angiography during the years 1950 to 1954 two died. Although in several instances the injury could be explained by repeated injections of contrast medium at the same investigation, there is no apparent reason in the others. Strict indications for these examinations are therefore necessary. The risks may be diminished by lessening the dose of the contrast medium. Renal function should be carefully checked before angiography is performed. The check should not be limited to determination of the nonprotein nitrogen only. Determination of the maximal concentration capacity combined with an Addis quantitative test would seem to supply more reliable information on the renal function.

Radiation Parotitis from Radioactive Iodine Therapy. R. G. Rigler and P. W. Scanlon. Proc. Staff Meet., Mayo Clin. **30**:149-153 (April 20) 1955 [Rochester, Minn.].

A woman came to the Mayo Clinic, Rochester, Minn., with a history of progressive pain over the left posterior aspect of the pelvis in the region of the sacroiliac articulation of some nine months' duration. This was associated with some limp and a sciatic type of extension of pain into the posterior aspect of the left thigh and occasionally into the calf. Roentgenograms of the pelvis revealed a well-demarcated area of lytic destruction involving the medial upper end of the left ilium adjacent to the sacroiliac articulation. On March 19, 1954, the posterior aspect of the left iliac crest was opened and a metastatic malignant lesion the size of a small fist was curetted. The pathological report of the curetted material was grade 1 (Broders' method) thyroid adenocarcinoma. The woman's physician stated that a left hemithyroidectomy had been performed in June, 1951, for removal of a 2 by 2 by 2 cm. tumor of the left upper pole of the thyroid. Tissue studies verified the clinical diagnosis of a malignant lesion. The patient had not been informed of the malignant character of the growth. Ten days after the removal of the metastasis from the ilium, the patient was given a 500 μc. tracer dose of radioactive iodine (I^{131}) in an attempt to ascertain whether or not there was any residual functioning thyroid tissue remaining in the ilium. A survey revealed a slightly increased counting rate over the lytic lesion in the ilium. Complete thyroidectomy was done on April 3, 1954, in an endeavor to stimulate the uptake of radioactive iodine by the metastatic growths in the ilium. Pathological examination of removed thyroid failed to reveal residual malignant tissue. Ten days after the thyroidectomy a second tracer dose of 300 μc. of I^{131} was administered. This likewise revealed very slightly increased activity over the lytic lesion in the ilium. It was felt that insufficient I^{131} was collecting in the metastatic growth to warrant administration of a therapeutic dose of I^{131}. A repeat tracer study in June again showed only a slightly increased uptake in the iliac lesion, but in view of the excretion pattern of the tracer dose it was felt that enough of the dose was being retained in the body to make administration of a therapeutic dose of I^{131} worth while. Consequently, on June 23, 1954, a 150 mc. dose of I^{131} was administered orally. This therapy was without immediate adverse effects except that 12 hours after the dose had been given the patient experienced bilateral symmetrical parotid swelling associated with moderately severe pain on opening the mouth or swallowing. The parotitis responded well to ice bags and salicylate therapy and completely subsided within the next 48 hours. In view of the fact that the patient had previously had viral mumps, it was felt that this syndrome was unquestionably radiation parotitis from I^{131} therapy, a condition the authors had not previously encountered. A perusal of the literature failed to reveal any mention of this entity as a complication of radioactive isotope therapy.

Roentgenotherapy of Backache and Sciatica. P. Pizon. Presse méd. 63:519-522 (April 6) 1955 (In French) [Paris, France].

Application of the technical factors involved in the absorption of x-rays by the soft tissues and bone to the problem of irradiating the lumbar spine (the last three lumbar vertebrae and the sacroiliac joints) for the relief of backache and sciatica shows that selective irradiation of the vertebrae can be obtained by using half value layer radiation between 0.7 and 1 mm. of copper with a focal distance of 40 cm. The total dose of 1,500 r to the skin (measured in air) should be given in 10 equal doses, and the best results are obtained when the first six sessions are given at the rate of three a week and the last four at the rate of two a week. Two parallel fields, 6 by 17 cm., should be used, each receiving half the total dose, or 750 r. The size of the fields should be reduced to 3 by 15 cm. to avoid any possible damage to the ovaries when the patient to be treated is a young woman and the half value layer radiation should then be equal to or less than 0.7 mm. of copper. None of the 97 women in the author's series of 205 patients showed any postradiation disturbance of menstrual function. Immediate cures were obtained in 62% of the patients, 155 of whom had backache and 50 true sciatica; 29.7% were improved; and only 8.3% were therapeutic failures. Roentgenotherapy thus remains the most effective and least injurious method of treating acute or chronic backache and sciatica. The common term found in all the processes that give rise to the pains of essential backache and sciatica is the existence of a neurovegetative, or more precisely a sympathicotonic, disturbance resulting from a change in intervertebral mechanics. The sympathicolytic effect of x-ray treatment suppresses the reflex vasomotor reaction and so puts an end to the ischemia and edema provoked by the neuroendothelial irritation of the synovial capillaries and the meninges. The efficacy of the treatment depends on the coordinated use of the x-rays, analgesics, general antirheumatic therapy, and local measures designed to correct osteoarticular defects in the spine. Failure occurs only when the irritative reflex is reestablished by premature resumption of physical activity or because the predisposing mechanical conditions have not been corrected.

Observer Error in the Interpretation of Photofluorograms and the Value of Dual Reading in the Danish Mass Campaign. E. Groth-Petersen and A. V. Møller. Acta tuberc. scandinav. 30: 209-230 (No. 3-4) 1955 (In English) [Copenhagen, Denmark].

The authors' past experience with experimental multiple reading of photofluorograms showed that individual differences in interpretation are great and a significant number of lesions are overlooked in routine interpretations by a single observer. Each of four experienced tuberculosis specialists failed to detect 32% of the total number of subsequently verified, clinically significant, pulmonary changes recorded in the photofluorograms. There was also a great deal of overreading. Dual reading of the photofluorograms was introduced as the routine method in the mass tuberculosis campaign in Denmark. The first reading was made, as before, at the local chest clinics by the chief physicians or qualified assistants. The second reading was made by central readers who did not see the report of the first reading. All suspected pulmonary lesions were checked by large roentgenograms at the chest clinics, where preliminary roentgen diagnoses were made and the necessary follow-up steps taken. The present study was based on 455,000 35-mm. films from 12 different counties. The readers found suspected lesions in the lungs of 10,905 persons (2.4%), but the first and second readers were in agreement on only 35% of the findings, varying from 20 to 45% in the various counties. The chest clinic examination at once found active tuberculosis requiring treatment in 306 patients, but only 257 of these cases were discovered by the first photofluorogram reader. Thus the second reader added 49 patients, an increase of 19%. In the second reading 16 patients were overlooked, so that a total of 65 of these cases of tuberculosis were recognized by only one of the photofluorogram readers. Tubercle bacilli were found at once in 56 of the missed patients. The chest clinic examination also revealed 2,918 other pathological lung changes that were considered to be clinically significant, i. e., requiring treatment or observation, but only 2,035 of these had been detected by the first reader; the second reading added 883, an increase of 43%. In the remaining 7,257 persons reporting for further examination at the chest clinic, either nothing abnormal was found or, in a small number of cases, pulmonary changes that were considered to be definitely healed were observed. Thus, of the 10,481 checked positive photofluorogram findings, 7,257 must be described as "false positive" and 3,224 as "true positive." Dual reading resulted in an overreading of 2.25 false positives to each true positive. The result of the first reading alone was 2.14 false positives to each true positive. Thus the increase of the relative overreading caused by dual reading was not significant. A systematic reader difference that is of interest in the future clarification of sources of error was noted. It is concluded that, though dual reading is far from an ideal solution to the problem of checking errors, the help it provided was great enough for it to become generally applied.

Roentgen Diagnosis of Small Polyps in the Colon and Rectum. L. Andrén, S. Frieberg and S. Welin. Acta radiol. 43:201-208 (March) 1955 (In English) [Stockholm, Sweden].

Of 1,274 patients who were subjected to colonic examination with the so-called double-contrast enema technique, one or more polyps were detected in 159 (12.5%). This technique consists of the combined use of a fairly dense contrast medium (50 mg. of dioxyphenylisatin [Neodrast] and 1,950 mg. of lactose) and of insufflation of air into the intestine with the aid of a clyster pump. The polyps were localized in the rectum in 99 patients. Of the total number of 214 polyps observed, 191 (90%) were less than 1 cm. in diameter and 132 (60%) were less than 5 mm. in diameter. The increased incidence of polyps in the authors' patients as compared with that reported by other workers may be ascribed to the fact that the authors largely succeeded in detecting the smaller polyps. This was probably the result of teleroentgenography combined with the use of fine focus tubes and a dense contrast medium.

Gas Embolus as a Roentgen Sign of Fetal Death. E. Samuel and K. Gunn. Am. J. Roentgenol. 73:974-978 (June) 1955 [Springfield, Ill.].

In fifteen cases of fetal death roentgenologic examination revealed intravascular gas in three main portions of the fetal cardiovascular system, namely, in the heart, the umbilical cord, and the fetal vessels. Intracardiac gas was present in all 15 cases; gas in the umbilical cord was observed in 5, and gas was present in the abdominal vessels in 9. No gas was demonstrated in the pulmonary or cerebral vessels in any case. Intravascular gas is not an infrequent sign of fetal death. It is postulated that gas in the fetal intravascular tree is not necessarily a late sign of fetal death since it occurred in five of the authors' cases before the conventional and well known roentgenologic signs (Spalding's sign and Hartley's Ball sign) had appeared. In 5 of the 15 cases, intravascular gas was the only roentgenologic sign of fetal death. Gas in the fetus arises not necessarily as a physicochemical change in the blood elements but rather results from a disturbance in the potential gradient between the maternal and the fetal blood pressures. The frequency with which gas is located in the heart itself suggests that the amount of gas may be sufficient to account for the actual cause of death, i. e., that the fetus actually dies from an intracardiac gas embolus. The possibility of the Rh factor as the cause of the underlying placental change is considered, and it is noted that in one case extensive placental calcification was shown.

A Clinical Investigation of the Chronic Effects of Radium Salts Administered Therapeutically (1915-1931). W. B. Looney, R. J. Hasterlik, A. M. Brues and E. Skirmont. Am. J. Roentgenol. 73:1006-1037 (June) 1955 [Springfield, Ill.].

The chronic effects of radium salts administered therapeutically until 1932, at which time radium for internal administration was removed from listing in the New and Nonofficial Remedies of the American Medical Association, were studied in 19 schizophrenic patients who between 1930 and 1931 were given intravenous injections at weekly intervals with a soluble salt of radium in doses of 10 mcg. of the element. The total doses ranged from 70 to 450 mcg. An additional 20 patients who had received radium orally, intravenously, or intramuscularly as a therapeutic procedure from 20 to 30 years ago and 6 radium dial painters were studied. Total retained radium and radon/radium ratios were determined in all patients and roentgenographic examination of the entire skeleton was done on all patients. The results of hematological studies carried out in 24 patients were neither striking nor diagnostic of radium poisoning. Roentgenograms showed a general correlation between the level of body burden of radium and the frequency and severity of osseous lesions. At body burdens of 0.4 mcg. or more clinically recognizable and unique bone lesions were present. These lesions increased in number, in extent of distribution throughout the skeleton, and in severity with increasing body burdens of radioactivity. No patient who received radium salts exclusively by the parenteral route (and thus probably received only radium) developed a bone neoplasm attributable to the presence of radium in the skeleton, but significant nonneoplastic lesions were observed in those persons containing as little as 0.4 mcg. of what was shown to be only radium salts, uncontaminated with more than 0.66% mesothorium. The osseous lesions revealed by the roentgenograms were classified in three groups. The significant minimal roentgenographic lesions in group 1 consisted of multiple 1 to 2 mm. by 5 to 20 mm. areas of decreased density occurring with great frequency and located most prominently in the fibula, tibia, radius, ulna, humerus, and femur. Related lesions were "punched out" areas of decreased density in the skull that closely resembled, but had to be differentiated from, the lesions of multiple myeloma. When the small areas of decreased density in the long bones became multiple, they lent a streaked appearance to the bone. The importance of these areas of decreased density lies in the fact that they could be noted in patients who were asymptomatic, in the absence of other more marked lesions, and that they occurred with a lesser body burden of radium than any other lesion. The lesions in group 2 consisted of areas of apparently increased density associated closely with areas of decreased density and showing varying degrees of change in trabecular pattern that were characteristic of this group. Group 3 included certain major changes that may be described as areas of aseptic necrosis, often with sequestration, occurring in certain sites of predilection, such as the head of the femur, the mandible, tarsal scaphoid, and vertebral bodies. Taken by itself, the appearance of one of these areas of aseptic necrosis in an otherwise apparently healthy adult is not diagnostic of radium poisoning but is suggestive.

PHYSIOLOGY

Thrombopenic Index in Allergic States. H. Storck. Semaine hôp. Paris 31:1897-1902 (May 30) 1955 (In French) [Paris, France].

The use of the thrombopenic index as an indicator of an allergic reaction in man is based on the fact that the number of thrombocytes is reduced by from 15 to 40% in the peripheral blood 90 minutes after exposure of the patient to the allergen. Patients who are not in an allergic state show only slight variations in the number of thrombocytes. This specific thrombocytic reaction is produced by exposure to alimentary, inhalatory, and drug allergens, as well as by those that are infectious in character. The present report deals only with drug allergies. The offending agent can usually be readily identified in cases of simple drug allergy, but in certain conditions, e. g., various forms of purpura, agranulocytosis, asthma, etc., in which withdrawal of all the active medications whose allergic effect is unknown might lead to a fatal aggravation of either the primary or the secondary condition reliable tests have a decisive practical value. Study of more than 200 patients with many different forms of drug allergy showed that the thrombocytopenic index is both reliable and specific. A few precautions, however, should be observed in applying the test: the technician should be experienced in counting thrombocytes by means of a phase microscope, and the fact that certain drugs, notably histamine and adrenaline, have an effect on the thrombocyte count, regardless of sensitization, should be kept in mind in interpreting the results. In vitro studies show that agglutination of the thrombocytes is increased when an allergen is added to oxalated blood. A high index of agglutination is found in sensitized patients. Comparison of the agglutination index with the in vivo decline in the thrombocyte level shows a definite parallelism between the two, with an agglutination index of from 1.4 to 2 corresponding to a reduction of from 15 to 40%. The active principle in the agglutination phenomenon is a thermolabile, dialyzable, specific factor that is contained in the patient's serum and that acts in the presence of a complementary thermolabile, nondialyzable, nonspecific factor. The in vitro test is especially valuable because it makes it possible to obtain a specific diagnosis without exposing the patient to the dangers of contact with the allergen. Both the agglutination and the thrombocyte-reduction tests are negative in nonsensitized persons.

The Physiology of the Aging Process in the Musculoskeletal Apparatus. E. M. Bick. Geriatrics 10:274-277 (June) 1955 [Minneapolis].

This study brings into focus certain aspects of the physiology of the aging process of the musculoskeletal system that apply to geriatric orthopedics. It deals with the process of physiological senescence and does not refer to the relative frequency of specific trauma or inflammatory joint disease in the elderly patient whose life has been exceptionally rugged, or the obese patient suffering from mechanically abnormal wear and tear of the articular tissues. In the physiology of the normal aging musculoskeletal apparatus, articular cartilage is found to be the most stable. Articular cartilage is a relatively avascular tissue that, when not injured by major trauma or the repeated minor traumas of mechanically unsound joint function, is apt to persist undamaged well into the late decades. Muscle tissue remains all but unchanged except as its power is influenced by circulatory or central nervous system deterioration. The skeletal deformities of the aged are mostly due to the collapse of soft and brittle bone at its points of major stresses. Endocrine and metabolic deficiencies and systemic decrease in the peripheral vascular supply are the physiological substrata of diminishing bone production in the aging skeleton. These deficiencies and dysfunctions interfere with the synthesis and distribution of the chemical elements needed for the production of bone substance. Clinically speaking, because of these deficiencies aged bone is soft and brittle. These two physical defects produce most of the commonly manifested skeletal problems of aging persons. Among them are generalized osteoporosis, avascular necrosis at areas of maximum stress, fractures at the brittle neck of the femur, compression of the vertebral body, and, in the presence of faulty joint mechanics, collapse of subchondral bone. When failing osteogenesis in the aging person can be controlled or retarded, orthopedic defects will be largely prevented. The chief physiological problem of orthopedic geriatrics is the synthesis of bone protein.

BOOK REVIEWS

Industrial Dust: Hygienic Significance, Measurement, and Control. By Philip Drinker, S.B., Ch.E., Professor of Industrial Hygiene, Harvard School of Public Health, Cambridge, Mass., and Theodore Hatch, B.S., S.M., Professor of Industrial Health Engineering. Graduate School of Public Health, University of Pittsburgh, Pittsburgh. Second edition. Cloth. $10. Pp. 401, with 148 illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1954.

This long-awaited second edition of the definitive textbook on industrial dust amply fulfills all expectations. Much of the material is highly technical, as it must be for engineers and hygienists confronted with the thorny problems of identifying, measuring, controlling, or removing troublesome or noxious material, frequently of ultramicroscopic particle size. Nevertheless, physicians interested in environmental hygiene in industry or from the broader community aspects of air pollution will find this volume indispensable. The chapters of greatest interest to industrial physicians, pathologists, and respiratory physiologists are those covering the effects of dusts and fumes on man, descriptions of inert and toxic dusts, physiochemical factors in pneumonoconiosis, and dust retention in man. Practical experience, common sense, and a forthright acknowledgment that time and accumulating data change concepts of maximum allowable concentrations make the discussions of the dusty trades particularly acceptable. Those interested in a critical appraisal of the engineering sections would do well to consult reviews in appropriate engineering or industrial hygiene publications.

You and Your Child's Health. By Paulette Kahn Hartrich. Foreword by Milton I. Levine, M.D. Cloth. $3. Pp. 208. Harper & Brothers, Publishers, 49 E. 33rd St., New York 16, 1955.

Designed for parents in order to help them to understand their child's reaction to the frightening experiences associated with sickness, this book could better be titled, "You and Your Child's Illness." The author tells the reader how a child establishes its feelings of security and certain relations to his parents and then points out what parents can and should do to strengthen and maintain these feelings during the trying periods that occur in childhood. Among the high points are discussions of the child's reaction to shots and other discomforts of child-physician relationships, the problem of the dentist, how to make a hospital experience less threatening, preparation for an anesthetic, family relations in chronic illness, and a host of other situations that can undermine the child's attitude toward his world. Though this book is basically a book for parents, it should be helpful to physicians who treat children and to all of the professional people associated with the physician in child care. Many of these suggestions may be new and certainly will furnish a review to those engaged in child health service.

The Therapy of Skin Tuberculosis. By Gustav Riehl, M.D., Professor of Dermatology, University of Vienna, and Oswald Köpf, M.D., Assistant, Department of Dermatology, Wilhelminen Hospital, Vienna. Translated and revised by Ernest A. Strakosch, M.D., Ph.D., Director, Department of Dermatology, Presbyterian Hospital, Denver. Publication number 229, American Lecture Series, monograph in Bannerstone Division of American Lectures in Dermatology. Edited by Arthur C. Curtis, M.D., Chairman, Department of Dermatology and Syphilology, University of Michigan, Ann Arbor. Cloth. $6.75. Pp. 247, with 8 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1955.

This monograph presents the treatment of tuberculosis of the skin in great detail. Inasmuch as tuberculosis of the skin has become somewhat uncommon in routine dermatological practice in the United States, it is fitting that this volume has been written by several of the outstanding European authorities on the subject. The major chapters are concerned with the techniques and rationale of vitamin D therapy. The remaining sections present the authors' experience with thiosemicarbazone, *p*-aminosalicylic acid, isoniazid, physical and surgical techniques, and general supporting measures. At the time of publication, the authors had probably not used pyrazinamide, cycloserine, or some of the newer drugs yet to be evaluated in the therapy of skin tuberculosis. Although the text is detailed and exceedingly thorough, the writing is ponderous and heavily interspersed with references and observations of a distracting nature. Much of this material could have been condensed or deleted to the advantage of the book. The format is pleasing. The illustrations are few and well chosen. The book is recommended for dermatologists and investigators interested in the therapeutic management of tuberculosis of the skin.

Physicians' Office Attendants Manual. Section for Office Work. By Henry B. Gotten, M.D., Associate Professor of Medicine, University of Tennessee, Memphis. Section for Laboratory Work: By Douglas H. Sprunt, M.D., Professor of Pathology, University of Tennessee. Cloth. $3.75. Pp. 93, with 15 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1955.

This book, written by an internist and a pathologist, covers many important and many seemingly unimportant bits of information. Its greatest value for a physician training his own office assistant may well be in the unimportant information—the things he forgets to talk about. The first portion of the section for office work contains good general information, easily understood, and one reading should suffice. The second portion, however, becomes a reference text with detailed information on the setup for certain examinations. The entire section for laboratory work is well written, and the detailed instructions can be used for reference. This book should be valuable to every physician who employs medical assistants.

Analytical Cytology: Methods for Studying Cellular Form and Function. Edited by Robert C. Mellors, M.D., Ph.D. Foreword by Francis O. Schmitt, Ph.D. Cloth. $15. Various pagination, with illustrations, Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1955.

This book covers the major physical and chemical methods currently in use in study of cell morphology and function. There are nine chapters: Cytophotometry by Pollister and Ornstein; Cytochemical Staining by Novikoff; Phase-Contrast, Interference-Constrast, and Polarizing Microscopy by Barer; Ultraviolet Microscopy and Microspectroscopy by Nurnberger; Fluorescence Microscopy by Richards; Electron Microscopy by Selvy; Radioautography by Fitzgerald; Historadiography by Engström; and X-Ray Diffraction Techniques by Oster. This book should be of great value to workers interested in the newer physical approaches to cytology. Principles as well as methods are thoroughly and competently presented and are made understandable without detailed physical and mathematical discussions. Although much of this material is available elsewhere, it will be found very helpful to have it collected in one volume.

Cellular Metabolism and Infections. Edited by E. Racker. Symposium held at New York Academy of Medicine March 4 and 5, 1954. Symposia of Section on Microbiology, New York Academy of Medicine, number 8. Cloth. $4.80. Pp. 196, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1954.

This small book makes no systematic attempt to assemble the available data on the pathology of infections at the metabolic level but includes a series of discussions, often unrelated to each other, that fall into two areas: (1) selected topics of comparative biochemistry, emphasizing differences in structural and metabolic patterns in hosts and parasites, and (2) selected aspects of the metabolism of infected cells. The participants in the symposium include many outstanding workers whose fields of investigation overlap, to varying degrees, under the title of this volume. Specific topics include energy production, formation of

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

adaptive enzymes, metabolic approaches to chemotherapy, cytochemical and biosynthetic events in bacteria infected with phage, and alterations of cellular metabolism during virus infections of animals and bacteria. This book is not meant for the practicing physician but rather for the research worker and the scholar. It is concerned with an important field in which much remains to be done before even data already available can be coherently integrated. The symposium will stand as a record of how, in 1954, investigators viewed the biochemical problem of infection at the cellular level.

Poliomyelitis. Contributors: Robert Debré et al. World Health Organization, monograph series no. 26. Cloth $8. £2; 24 Swiss francs, Pp. 408, with illustrations. Columbia University Press. 2960 Broadway, New York 27; World Health Organization, Palais des Nations, Geneva, Switzerland, 1955.

This monograph presents the progress of research, the ideas, and the explanations that have accrued in the past 15 years. Facts critically appraised and fully documented serve either to introduce the reader to the field or to acquaint those already in it with the present trends and the direction of future progress. The vast literature has been well covered in the five sections on epidemiology, clinical aspects, virology, immunology, and control. Each section ends with succinct conclusions. Except for the section on control, each of the five subjects is divided into three parts, each discussed by eminently qualified authors, who review their subjects in the light of their own experiences in nine different countries from the standpoints of clinical observations, intensive and prolonged research, or international public health.

The reasons why poliomyelitis is now regarded as a highly infectious, frequently epidemic disease of civilization with the alimentary tract as the primary portal of entry are fully explained by John R. Paul (United States). Surveys conducted in Africa and elsewhere by J. H. S. Gear (South Africa) have shown that, where poliomyelitis is endemic or hyperendemic, most of the clinical infections occur among children. Under these conditions, as in most infectious diseases, poliomyelitis tends to be less severe and, in this case, less likely to cause paralysis. The epidemicity grows with advances in hygiene and living standards, and it then attacks adults. As M. J. Freyche and J. Nielsen (World Health Organization, Geneva) emphasize, it cannot then fail to bring about a higher case fatality rate. The section on the clinical aspects, written by Robert Debré and Stéphane Thieffry (France), the management of acute poliomyelitis by W. Ritchie Russell (England), and the management of respiratory and bulbar paralysis by H. C. A. Larsen (Denmark) offer the practitioner information in synoptic form. The text is amplified by good illustrations and a table on the therapeutic results in life-threatening poliomyelitis. The review on the physical and chemical characteristics of the virus by S. Gard (Sweden), aside [illegible]m presenting evidence that the viruses of this group are [illegible]ng the hardiest of all known animal viruses, directs attention [illegible] many insufficiently studied subjects of practical importance. With the new tools made available by the tissue culture method developed by John F. Enders (United States), the solutions of many of the problems are brought into reach. Even a casual glance at the chapter on diagnostic tests by A. J. Rhodes, W. Wood, and Darline Duncan (Canada) impresses the reader with the progress made in recent years. The four annexes to this chapter pool the experiences of many virologists and thus furnish conveniently the only up-to-date presentation of many of the procedures now in use. As a background to enable the physician to better understand the problems involved in vaccination, the chapter by A. B. Sabin (United States) deserves careful reading. Principles and objectives are clearly outlined, and the merits of vaccines made with killed virus are compared with those made with living, avirulent variants. In a companion article Hilary Koprowski (United States) discusses his initial studies on the immunization of human subjects with an orally administered attenuated strain. The procedure itself is safe for the vaccinated, and the degree of elicited antibody response indicates that this procedure may warrant more exploratory field trials with other attenuated types. Such studies are now in progress. Many of the questions raised by authors with respect to the alimentary carrier state established by this method await an answer. According to W. McD. Hammon (United States), gamma globulin supplies a low level of antibody and is temporarily preventive under certain conditions but has a limited field of wide-scale application. Although effective in limited control field trials, the dosage factor, not yet determined, is of great importance. In his review of the public health measures, A. M.-M. Payne (World Health Organization, Geneva) discusses all the well-known, general, and specific procedures to reduce the spread of infection, the nonspecific factors influencing the incidence of paralysis, the role of the laboratory, and the essential position of active immunization. He concludes that, as procedures for active immunization become available, they should be supported by measures designed to reduce the amount of virus in the environment.

A carefully prepared index and the excellent printing and binding make this handy volume attractive and most useful to the library of a practicing or research physician and an excellent reference for the student.

Essentials of Orthopædics. By Philip Wiles, M.S., F.R.C.S., F.A.C.S., Senior Orthopædic Surgeon, Middlesex Hospital, London. Second edition. Cloth. $10. Pp. 538, with 400 illustrations. Little, Brown and Company, 34 Beacon St., Boston 6, 1955.

This is an excellently arranged textbook. The printing is of such size as to make easy reading and the many illustrations add a great deal to understanding the text. The drawings are particularly well done. If criticism were to be given this phase, it would be that the x-ray reproductions on the whole do not come up to what we have been accustomed to seeing in British books. Many of the x-rays are not clear, but others are very good. We probably have been spoiled in the past with the excellence of British x-ray reproduction. The colored drawings are superior in quality. The book itself is written in typical, clear-cut British style and makes for very interesting reading. It is not too technical so that the book has definite application both to the medical student as well as to those on advanced training status and certainly is a good book for every orthopedist to have in his library.

The references are almost solely to other British authors with only occasional reference to American authors. This does not detract from the book but again shows the author's close relationship to his local colleagues. There is little in general with which one can disagree, with a possible exception being the treatment recommended for tuberculosis. More authors and investigators in the United States are treating tuberculosis surgically than is indicated in this book. The author continues to hold the extreme ultraconservative British view on this subject. The opinion expressed here does not detract from the value of the book in any way but merely emphasizes the author's own management of this disease. The size of the book is handy. It does not become burdensome to hold and one does not realize that it is over 500 pages. This ease of handling facilitates using the book for frequent reference.

Practical Endocrinology. By Lewis M. Hurxthal, M.D., Head of Department of Internal Medicine, Lahey Clinic, Boston. In cooperation wit A. Seymour Parker, M.D., Physician, Department of Internal Medicine Lahey Clinic, and Hirsh Sulkowitch, M.D., Research Associate, Lahe Foundation. Handbooks for general practitioner. Cloth. $7. Pp. 318 with 17 illustrations. Landsberger Medical Books, Inc., distributed solel by Blakiston Division of McGraw-Hill Book Co., 330 W. 42nd St., Ne York 36, 1955.

This book has no pretension of being an exhaustive text i endocrinology but instead successfully presents to the practicin physician the diagnosis and treatment of the endocrine cond tions he is likely to meet in practice. The arrangement of th text varies somewhat from the usual, considering first the dia nosis and treatment of the endocrine disorders of infancy an childhood, then the endocrine disorders associated with th major endocrine glands. Special chapters are devoted to hype insulinism, gynecomastia, and female hirsutism. The availab hormones and their use in general practice are also considere Most intriguing is the chapter on office laboratory tests. Th familiar Sulkowitch test, the circulatory eosinophil, lymphocyt and sperm count techniques, as well as the iodine vapor meth for staining vaginal smears are described and seem well withi the capacity of the average physician's office laborator The assay of 17-ketosteroids by the Callow-Talbot-Sulkowit method is another matter and seems out of place in this text, since it would require suction apparatus, preparation of a fresh standard solution each day, a reflux condenser, a colorimeter, and, most important of all, hours of time and correction for interfering chromogens by means of a complicated calculation. Nevertheless this is a practical text and a most valuable, clear, and not too complex presentation of endocrine problems encountered by the general practitioner.

Pain: Its Mechanisms and Neurosurgical Control. By James C. White, M.D., F.A.C.S., Chief of Neurosurgical Service, Massachusetts General Hospital, Boston, and William H. Sweet, M.D., F.A.C.S., Associate Visiting Neurosurgeon, Massachusetts General Hospital. With assistance in psychiatric sections of Chapters IV and X from Stanley Cobb, M.D., and Frances J. Bonner, M.D., Assistant in Psychiatry, Massachusetts General Hospital. Cloth. $17.50. Pp. 736, with 134 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1955.

The treatment of severe pain by surgical means is a fairly recent innovation. Only in the last 20 years has the subject grown to sufficient size to warrant a book such as this. The authors have analyzed the records of 420 patients suffering from persistent severe pain on whom operation was justified. Most of the patients were seen between 1935 and 1949, but a few, particularly those with cardiac pain, go as far back as 1927. The clinical material since 1950 has not been analyzed, as the authors, quite justifiably, wish to have at least a five year follow-up period before reaching a conclusion in regard to the efficiency of any particular procedure. The first part of the book discusses the fundamental aspects of pain in the end organs and the afferent tracts to the central nervous system. Care is taken to evaluate also the psychiatric aspect of pain, particularly the neurotic component so frequently a disturbing factor in the treatment of patients with pain as the presenting symptom. A second part of the book deals with surgical techniques such as nerve block, neurectomy, rhizotomy, and the interruption of pain pathways in the spinal cord, medulla, and elsewhere in the nervous system. The third section discusses specific painful conditions such as the neuralgias of the peripheral nerves, amputation stumps, phantom limbs, trigeminal neuralgia, and cephalic pain, with a special chapter on painful conditions associated with the thoracic viscera, particularly the heart, aorta, and lungs, and a second chapter on abdominal visceral disease. The bibliography is extensive; there is an ample index by author and subject; the illustrations are adequate; but some of the case records are given in more detail than seems necessary for a book having a general appeal. Certain of the work sheets used might be omitted in future editions, as they are printed as attached tables folded into the book and thus particularly vulnerable to hard usage. The book in general would be improved by the deletion of much that is repetitious, and part of the working material would not be missed if omitted except by a few special students. The authors, leaders in the field of neurological control of pain, have written an outstanding book that sets an excellent pattern in a relatively new but ever-increasing aspect of the treatment of disease.

The Biologic Effects of Tobacco with Emphasis on the Clinical and Experimental Aspects. Edited by Ernest L. Wynder, M.D., Head, Section of Epidemiology, Sloan-Kettering Institute for Cancer Research, New York. Foreword by Joseph Garland, M.D. Cloth. $4.50. Pp. 215, with 20 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1955.

The expressed purpose of this book is to determine what is fact and what is fancy about the possible relationship of tobacco and tobacco smoke to human health. The evidence for and against smoking as a calculated risk to health is assembled in eight well-written, well-documented chapters. These deal with the chemistry and pharmacology of tobacco and its relationship to the cardiovascular system, neoplastic diseases, the gastrointestinal tract, and allergic phenomena. An important chapter, called Cause and Effect, dwells on the significance of statistics in establishing some of the associations described.

For some time medical and public attention has been focused on the relationship of smoking and cancer of the lung. There has been a tendency to overlook some of the other effects of smoking on human health, which, in the long run, may eventually prove more significant than the question of lung cancer. For example, relatively little attention has been paid to the relationship of tobacco smoking and the cardiovascular system, at least by a large part of the medical profession and most of the general public. In this connection, it is noteworthy that the direct effect of nicotine in smoking tobacco may be demonstrated by changes in the electrocardiogram, skin temperature, ballistocardiogram, and blood flow (plethysmographic, retinal, and peripheral capillary). The simultaneous use of alcohol will not effectively counteract the effect of smoking on the cardiovascular system. Although there is no evidence that tobacco is an etiological factor in peripheral arteriosclerosis, hypertension, cerebral vascular disease, coronary artery disease, or Raynaud's disease, there is, on the other hand, evidence that, once these diseases are established, the use of tobacco unfavorably influences the clinical course. The use of tobacco by susceptible persons will result in the development and continued activity of thromboangiitis obliterans. Finally, neither protective filters nor denicotinization to the degree now practiced have eliminated the deleterious effect of tobacco on the cardiovascular system.

As a summary of current knowledge affirming or denying tobacco as a factor in human diseases, this book is highly recommended. It is a basic reference work for physicians who want to determine whether they should advise their patients to smoke or not to smoke, and under what circumstances.

Kinesiology of the Human Body under Normal and Pathological Conditions. By Arthur Steindler, M.D., F.R.C.S., F.A.C.S., Head of Orthopaedic Department, Mercy Hospital, Iowa City, Iowa. Cloth. $19.75. Pp. 708, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1955.

After 8 introductory chapters on the mechanical properties of bone, muscle, and related tissues, there follow 7 chapters on the trunk, 21 on the extremities, and 2 on the mechanics of normal and abnormal gaits. There is material of value to the physiologist in the discussions of the mechanics of respiration, the dynamics of the vertebral column, and the normal gait. The minute descriptions of the effects of sprains, fractures, and paralyses in various parts will interest orthopedists and neurologists. This book contains a wealth of instructive illustrations, a collection of references at the end of each chapter, an author index, and a subject index. It represents much hard work and will be helpful to mature students of neurology, orthopedics, and rehabilitation.

Handbook of Pediatrics. By Henry K. Silver, M.D., Associate Professor of Pediatrics, Yale University School of Medicine, New Haven, Conn., C. Henry Kempe, M.D., Assistant Professor of Pediatrics, University of California School of Medicine, San Francisco, and Henry B. Bruyn, M.D., Assistant Professor of Pediatrics and Medicine, University of California School of Medicine, San Francisco. Cloth. $3. Pp. 550. Lange Medical Publications, P. O. Box 1215, Los Altos, Calif., 1955.

This book is small enough to be carried in one's back pocket. It does not contain complete information on the subject of pediatrics, and the authors do not make any such claim. There are a number of this type of textbooks already in circulation. Since the authors invite suggestions and criticisms, it might be pointed out to them that they should ask the publisher to use a much larger print, for it is extremely difficult to read this book for any length of time without becoming tired.

Ancient Therapeutic Arts: The Fitzpatrick Lectures Delivered in 1950 & 1951 at the Royal College of Physicians. By William Brockbank, M.A., M.D., F.R.C.P. Cloth. $5. Pp. 162, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., [n.d.].

This book describes several of the older therapeutic procedures that have dominated medical thought and practice for a number of centuries—the enema, cupping, leeching, the various methods of counterirritation, and, more recently, the intravenous injection of fluids, from the time of its invention down to the present day. The story is well told; the illustrations are informative and revealing; and the reader is assured of several hours of absorbing reading.

QUERIES AND MINOR NOTES

BLOOD TESTS BEFORE TONSILLECTOMIES

To the Editor:—*What is the status of doing routine bleeding time and coagulation time tests just before tonsillectomies? What is your opinion concerning the capillary tube coagulation test?*

M.D., New York.

Answer.—Shepeard (Uses and Abuses of Coagulation and Bleeding Time Preceding Tonsillectomy, *Texas State J. Med.* 44:35-37 [May] 1948) expressed aptly what is the present-day informed opinion regarding bleeding and coagulation time just before tonsillectomies: "This interest" [in clotting and bleeding time] "seems to me to be a vestigial remnant of yesteryear and to be out of proportion to its value when weighed against knowledge and teachings concerning the conditions in which the clotting and bleeding phenomena are apt to be abnormal." There have been numerous reports relating experiences from busy nose and throat departments that show without any doubt that bleeding and coagulation time estimations are not practical as tests predicting hemorrhages during or after tonsillectomy. Normal results are not a guarantee of freedom from hemorrhage, and abnormal results have been observed without subsequent bleeding. Dependence on bleeding and coagulation time tends to lead to a false sense of security. Much more important is a careful clinical history with emphasis on questions likely to bring out a bleeding tendency and/or other conditions, such as infections, that may be associated with excessive capillary fragility and so forth. A careful physical examination is also extremely important. Post-tonsillectomy hemorrhages have been shown to come from injury to major blood vessels. If history or physical examination suggest a bleeding tendency, then a thorough study of the blood is indicated. White and differential blood cell counts are certainly of greater potential value as a warning than coagulation and bleeding time alone. Capillary coagulation time is definitely less reliable than the Lee and White technique, because blood obtained by skin puncture is mixed with tissue juice and, therefore, is unsuitable for determining the clotting time.

EDEMA OF THE MACULA LUTEA

To the Editor:—*What is the pathogenesis of "edema of the macula lutea" and of formation of small central cataracts bilaterally at the posterior poles of the lens capsules? Does regular medication of Spansules of Dexedrine, 15 mg., prescribed in the same case for depressive postclimacteric anxiety neurosis have any deleterious effect on the macula edema, on the possible extension of the cataract formation in the lens capsule, or on the blood pressure in general?*

Martin Abraham, M.D., Cincinnati.

Answer.—Edema of the macula lutea occurring in a middle-aged patient and bilateral in its course is considered to be due to an angiospastic condition of the blood supply to the macula. The cause of the angiospasm is speculative, and there are some who claim that there is a psychogenic background in all cases; others believe that it is due to toxoallergic reaction. Another cause for the edema is inflammatory choroiditis producing edema and hemorrhagic extravasation in the macular zone. This is a form of granulomatous uveitis. Another condition producing macular edema is seen in so-called Kuhnt-Junius disease. This is the result of vascular sclerosis with a break in Bruch's membrane and extravasation of blood and serum beneath the retina. The cause of this is unknown but is definitely traced to diseased blood vessels. The formation of posterior subcapsular cataract may be the result of either low-grade uveitis or a congenital defect that progresses along with age. It is also known to occur after middle age as a form of senile cataract. So far as is known, no case of lens opacities or edema of the macula has resulted from the use of Dexedrine.

OYSTERS

To the Editor:—*What part of iron in oysters is utilizable iron? I have read that oysters are second only to liver as a good source of iron from food.*

Thomas Emmett Smith, M.D., Hayes, Virginia.

Answer.—The iron in oysters, as is the case with iron in most foods obtained from animals, is readily assimilated. Because of the high iron, manganese, and copper content, oysters have long been used in the dietary treatment of anemia. In addition to furnishing large amounts of iron, oysters are also rich in protein, being comparable to meat and eggs in this respect. Oysters are also abundant in vitamins A and D and contain significant amounts of thiamine, riboflavin, vitamin C, and calcium. An article entitled "Consideration of Nutritional Value of Oysters" appeared in the Oct. 11, 1941, issue of *Semana médica Española;* an abstract of this article appeared in the May 23, 1942, issue of The Journal, page 378. The author states that "in the dietary treatment of pernicious anemia, oysters can be estimated next to liver as a source of iron."

CALORIC REQUIREMENTS FOR CHILDREN

To the Editor:—*Please estimate the range of caloric expenditures for each age from 6 to 11 of school children who do the absolute minimum in physical exertion. Will you suggest a regimen for each age that would correct obesity and faulty posture? Would you expect a boy of 14 who has been fat for a few years and is now 50% overweight to thin out as he grows older without some change in his diet and habits? Is he a good life insurance risk? How much active play should a child have each day?*

P. Donald Grant, M.D., Outremont, Quebec, Canada.

Answer.—Calorie requirements are determined by the basal heat production, specific dynamic action of food (SDA), expenditure for temperature regulation, physical activity, and needs for growth. These determining factors vary with such data as age, sex, body size, environmental temperature, and adequacy of clothing. Hence, any range of calorie expenditure is but a rough approximation unless one specifies the several most important determining characteristics. For the age range 6 to 11 years, Macy (Nutrition and Chemical Growth in Childhood, Springfield, Ill., Charles C Thomas, Publisher, 1942, vol. 1, p. 148) observed a caloric intake of about 1,780 to 2,300 daily. Basal heat production accounted for 1,010 to 1,358 calories per day and the SDA an additional 10% above the basal. Energy for activity amounted to some 30 to 40% of the intake. Accordingly, an intake for a child at absolute minimum of activity would be somewhat above that of 1,200 to 1,500 calories. Values summarized by McLester and Darby in "Nutrition and Diet in Health and Disease" (ed. 6, Philadelphia, W. B. Saunders Company, 1952, p. 47) estimate the average requirement of a "very quiet boy" from 6 to 11 years old as ranging from 1,600 to 2,000 calories. The intake conforming to the conditions set by the inquirer would probably lie between the estimates from these two sources. Obesity in children is usually a manifestation of maladjustment. Successful control should determine the underlying psychological basis and bring about correction of it. This includes such factors as consideration of the family relationships, the adjustment and acceptance of the child by other children, and the abilities of the child as compared to those of his associates. As Bruch (*Bull. New York Acad. Med.* 24:73 [Feb.] 1948) notes, food stands for love, security, and satisfaction and, hence, has an exaggerated positive value for some maladjusted, insecure individuals. Conversely, activity and social contacts are

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

associated with insecurity, threat, and anger. Stringent restriction of calories is usually not required, but a reduction of intake to 1,200 to 1,600 calories with correction of food habits will result in a failure to gain weight, if not an actual loss. If the disproportion between height and weight is not too great, it will readjust as the child grows. If physical disability prevents normal activity, more rigid reduction in caloric intake may be required. The greatest obstacles to successful reduction of calorie intake are oversolicitous parents or grandparents, family eating patterns that result in excessive caloric intakes, and the temptation of candy, nuts, soft drinks, and the like. The 50% overweight boy of 14 years probably will not thin out unless some corrective measures are instituted. The increased health risk of the obese child is less well established than for the adult. While there is no practical method for quantitating active play, it is commonly observed that the healthy, well-adjusted boy of 6 to 11 years enjoys three to five hours of ball playing, swimming, competitive games, riding, hiking, and the like per day. Girls may be somewhat less active.

TACHYCARDIA

To the Editor:—*Please tell me the effects of Rauwolfia on paroxysmal tachycardia and the effects of Veratrum when quinidine is being used.*

Edwin M. Meek, M.D., Greenwood, Miss.

Answer.—There seems to be as yet no extensive experience with the effect of Rauwolfia serpentina on paroxysmal tachycardias. However, it has been reported as helpful in suppressing cardiac irritability in a few cases and deserves more extensive trial (*J. A. M. A.* **157**:946 [March 12] 1955). Quinidine has a "vagolytic" effect on the heart similar to atropine and, in addition, acts directly on heart muscle to increase refractory period and slow conduction. In toxic doses sinoatrial block, atrioventricular block, and ventricular ectopic rhythms may appear. Because of the blocking action on the vagus, quinidine would tend to lessen or prevent the bradycardia usually seen following the administration of effective doses of Veratrum preparations. Large doses of Veratrum may also cause nodal or ventricular tachycardia. Therefore it would seem unwise to add Veratrum in high dosage to the treatment of a patient already receiving quinidine to the limit of tolerance.

POSSIBLY GOUT

To the Editor:—*A woman developed gout many years prior to menopause. The gout has apparently become much worse since. Even minute doses of colchicine produce diarrhea. She also has severe recurrent bouts of vomiting and has asthma, cerebral atrophy with convulsive seizures, and petechial hemorrhages about the skin. The blood cell count is normal. She shows a poor response to Butazolidin even when it is combined with corticotropin.* *M.D., Alabama.*

Answer.—In a patient with symptoms as complicated, especially a woman whose disease antedated menopause, it is essential to be certain that the diagnosis of gout is correct. For example, the coincidence of asthma, convulsions, petechial hemorrhages, and joint disease strongly raise the possibility of periarteritis nodosa. Serial uric acids should be drawn, together with a nonprotein nitrogen test inasmuch as hyperuricemia may accompany renal insufficiency. Skin and muscle biopsy may also be in order. Because of the lack of symptomatic benefit from the medications listed and because of uncertainty as to the diagnosis, a good trial of salicylates should be used. Aspirin should be given to the point of tolerance; between 3.6 and 7.2 gm. daily is usually required. Should the diagnosis of gout be definitely established, and a uricosuric agent be desired, Benemid could be given in a dose of 1 or 2 gm. daily. The dose should be determined in each individual patient by measuring the serum uric acid and daily urinary excretion of uric acid. The drug is usually given indefinitely. Fluids should be forced to reduce the chance of renal stone formation. Since salicylates interfere with the uricosuric effect of Benemid, analgesic effect must be obtained through the use of colchicine, Phenacetin, or other drugs other than salicylates.

ERUCTATION OF HYDROGEN SULFIDE

To the Editor:—*What is the significance of the eructation of hydrogen sulfide? This usually occurs in association with a gastrointestinal upset such as nausea and diarrhea. During the past year the patient has had several recurrences. One stool examination has been negative for ova and parasites. A small gastric diverticulum is present.* *M.D., Alabama.*

Answer.—The eructation of hydrogen sulfide is one of the symptoms of intestinal obstruction. It is one of the strong constituents of the "fecal odor" that is pathognomonic of intestinal obstruction. In the absence of obstruction, it is conceivable that a regurgitant phenomena might produce this symptom. Sulfur is ingested mainly as the amino acids—cystine and methionine of meats. Foods also contain inorganic sulfates, especially sodium and potassium sulfates. Small gastric diverticula are usually of little clinical importance and probably of no importance in this case. It would be interesting to reduce the protein intake during this patient's episodes of eructation. A low protein diet should be helpful if the ethereal sulfides are of exogenous origin.

IMPOTENCE

To the Editor:—*Regarding the development of impotence following urethral injuries, particularly as a complication of a fractured pelvis, I contend these are psychogenic or perhaps more properly, iatrogenic in origin. Please discuss.*

M.D., Canada.

Answer.—Certainly, impotence is most frequently psychogenic in origin, but the possibility of traumatic origin cannot be denied following extensive trauma secondary to a fractured pelvis. Urethral injuries involving the prostatic urethra may result in damage to nerve endings, either at the time of injury or at a later date due to scar tissue formation. Such damage may be sufficient to produce impotence. Since most urethral injuries in fractured pelvis involve the membranous urethra, or bulbous urethra, impotence from organic damage is unusual. Fracture of the pelvis may result in complete separation of the urethra, but the prostate usually remains intact and sensation to the verumontanum and ejaculatory ducts is likewise usually intact. Injury to the penile urethra may be accompanied by hemorrhage or later fibrosis of the cavernous bodies with difficulty in erection and secondary impotence.

ANEMIA DURING PREGNANCY

To the Editor:—*What is the current opinion on transfusion for hypoplastic anemia of 9 gm. per 100 cc. hemoglobin level in a six and one-half months' pregnant woman? Abnormalities in the baby are a problem.* *M.D., Oregon.*

Answer.—The usual anemia encountered in pregnancy is due to iron starvation and is likely to be normocytic or microcytic. As a rule it responds to the administration of iron. Usually transfusion is not resorted to unless the hemoglobin level cannot be maintained above 7 gm. per 100 cc. Blood transfusion is effective in raising the hemoglobin level, and when proper safeguards are exercised it can be carried out anytime in the pregnancy. There are no data that implicate blood transfusions in the causation of fetal abnormalities.

FRACTURE OF HIP IN AGED WOMAN

To the Editor:—*What is the usual management of an 84-year-old woman with a broken hip, and what is the prognosis?*

Adrian H. Scolten, M.D., Portland, Maine.

Answer.—If the patient is not in shock, fixation by a pin through the neck of the femur is best as soon as a diagnosis is made. An operation may be done under local or general anesthesia following reduction, depending on the operator's surroundings, experience, and skill. The leg is lightly cradled after operation, and every effort is made to return the patient to some activity at once, such as being lifted properly into a bedside chair or onto a commode. If any shock is present that forbids immediate pinning this must be treated. If recovery is prompt proceed as above. If irreversible, light traction on a broken limb plus meticulous nursing care is required. Any and all nursing care must be of highest quality to avoid decubitus and other complications such as exhausting pain from any movement. Pin fixation may be done after several days' preparation if the patient's temporary recovery warrants. In rare cases expert application of double-body plaster of Paris spica gives good prognosis if nursing care is adequate. Early mortality is around 25%.

PROTHROMBIN DETERMINATION

To the Editor:—*Has any practical procedure been developed for home prothrombin determination?*

R. Favour Jr., M.D., Bowdoinham, Maine.

Answer.—Many techniques of bedside prothrombin determinations are described in literature (e. g., "Micromethod for the Quantitative Determination of Plasma Prothrombin and Proconvertin," *Acta med. scandinav.*, vol. 150, 1954). None of these techniques is sufficiently simple that it may be performed reliably in the patient's home. If patients are to be treated with dicumarol, or drugs of similar action, while they remain at home, it is suggested that the one-stage prothrombin time test (Quick) be determined in the routine manner. Blood is drawn from the patient and then transported to a laboratory proficient in performing the test. If the test can not be performed within a few hours, addition of an accelerator (labile) factor is necessary to obtain valid results. Labile factor is prepared by adsorption of fresh normal plasma with barium sulfate. It should be emphasized that dicumarol treatment, if not adequately guided by trustworthy laboratory results, may lead to dangerous complications.

TREATMENT OF ABRASIONS

To the Editor:—*What is the accepted opinion on the use of tincture of merthiolate as adjunct treatment of abrasions and lacerations of the skin? Is the tissue destruction resulting from its presence in a wound of a sufficient amount to contraindicate its use as an antiseptic or a germicidal agent? Is there any clinical evidence to support a claim that greater risk of wound infection or delayed healing would result if tincture of merthiolate were to be applied to a laceration already prepared by débridement and the use of a good detergent prior to suturing?*

M.D., New York.

Answer.—In recent instruction courses under the aegis of one of the national dermatological societies, it was denied that the organic mercurial antiseptics possess any high germicidal value. Merthiolate, which is the sodium salt of ethyl mercury thiosalicylic acid and contains approximately 49% mercury, was included in the appraisal. It is recognized that under test tube conditions these mercurials exhibit high disinfecting properties, but on application to skin surfaces equal efficacy does not arise. In "Antiseptics, Disinfectants, Fungicides, and Sterilization," edited by Reddish (Philadelphia, Lea & Febiger, 1954), this same denial of high antiseptic properties for mercurials appears. Application for two minutes of 1:1,000 merthiolate only reduced the bacterial flora about 18%. Alcoholic solution of these mercurials was more effective than the corresponding aqueous solution, but the difference was attributed mainly to the antiseptic action of the alcohol. In fact, in some instances, the alcohol alone was more effective than the same alcohol with a mercurial disinfectant content. Of several mercurials examined merthiolate was reported of least value. Merthiolate, in the concentration commonly applied, little damages contact tissues although under rare conditions, such as brought about by the presence of acids, this alkaline solution may be precipitated with the liberation of damaging mercury. Although the application of any chemical disinfectant perhaps always involves a physiological compromise, in the case of merthiolate subsequent wound infection or delayed healing more likely may be attributed to antiseptic shortcomings rather than to significant tissue damage.

BLADDER IRRITABILITY

To the Editor:—*What is the treatment of interstitial cystitis in a 38-year-old woman in good general health and with no gynecology pathology, no signs of obstruction anywhere in the urinary tract, no discernible foci of infection, and no menstrual or hormonal abnormalities. For one and a half years she was treated with sedatives, silver irrigations, and urethral dilatation without any improvement. Cystoscopy shows edematous mucosa, but no ulcerations. There is no diminished capacity of the bladder, only frequency during the day, burning; and severe suprapubic and lumbar pain. Does the absence of frequency during the night rule out the diagnosis of interstitial cystitis?*

M.D., New York.

Answer.—Judging from your clinical findings, it is doubtful that the patient is suffering from interstitial cystitis. The absence of nocturnal frequency, as a rule, excludes such a diagnosis. Since interstitial cystitis almost invariably reduces the capacity of the bladder, a normal capacity, as in this case, would also rule it out. The fact that there is no ulceration in the bladder does not exclude interstitial cystitis. It may be assumed that there is some other factor to account for the patient's bladder symptoms. It is inferred, although not stated in the clinical data, that examination of the urine, including bacteriological study, was negative and that urography disclosed no abnormality. If this is the case, one should think of the possibility of an allergic condition, and a careful study of the patient should be made to exclude it. In some cases of bladder irritability of obscure origin, forcible dilatation of the bladder under an anesthetic, together with topical application of a concentrated solution of silver nitrate has been of therapeutic value. In order to exclude a malignant condition in the edematous mucosa of the bladder, it would be well to obtain a specimen for biopsy.

CIRCUMCISION IN THE FEMALE

To the Editor:—*Is circumcision in the female of any value in the treatment of sexual hyperesthesia or frigidity?*

M.D., New York.

Answer.—The operation of circumcision in the female is an unorthodox procedure that is a remnant of an ancient custom practiced chiefly in equatorial Africa. Many ancient tribes performed this as a ceremonial rite and often included the removal of part or all of the clitoris and a portion of the labia. It is not only a mutilating operation but is entirely unwarranted: it has no place in the regular practice of surgery or gynecology. No benefit is to be derived from female circumcision in cases of sexual hyperesthesia or frigidity.

PREGNANCY TESTS DURING HOT WEATHER

To the Editor:—*The answer in the June 11, 1955, issue of* The Journal, *page 519, regarding false-negative results using Xenopus laevis toads as pregnancy test animal is not complete. Shapiro and Zwarenstein* (Nature **133**:*762, 1934; Shapiro, H. A., and Duncan, D. G.* Clin. Proc. **3**:*186, 1944) discoverers of this test, give the following information. 1. During the breeding season (July to September in South Africa) it is necessary to isolate the test animals for at least one week, and controls should be killed and examined. 2. Toads kept in the laboratory longer than three to four weeks become insensitive to the injections, and false-negatives may be obtained. 3. Ovulation occurs in about 5 to 24 hours. If, after 24 hours, no ovulation has occurred, the animals are killed and a post mortem is performed to search for retained ova. They found that about 7% of positive reactions were oviducal positives. 4. Negative tests should be repeated in 10 to 14 days. 5. In spite of all precautions, every investigator, including the discoverers, have reported false-negative results.*

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY-AUGUST 1955

Abstracts have been made of important articles in the following journals in the Current Medical Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by the Library of the American Medical Association to individuals in Continental United States and Canada who subscribe to its scientific periodicals and to members of the American Medical Association and its student organization. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each periodical. Three journals may be borrowed at a time for a period not exceeding five days. Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "ab," abstracts; the asterisk (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word with the following exceptions: Foundations, Lectures, Moving Pictures, and Prizes, under "F," "L," "M," and "P" respectively. "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 56.

LITHIUM
  treatment of manic psychoses, Denmark, 327
LITTER
  fall from, woman 86 broke thigh, sued hospital, England, 1545
LIVER
  amebiasis, atabrine in, [Ghaffar] 86—ab
  amebiasis in guinea-pigs, abscess formation with persistent intestinal lesions; infection via mesenteric and portal veins, [Maegraith] 86—ab
  biopsy, histology in alcoholism, [Manghini] 615—ab
  biopsy (needle), diagnostic value, [Ward] 227—ab
  biopsy (needle), effectiveness and complications, [Morey & others] *1489
  biopsy (needle), glycogenosis and hepatic sclerosis revealed by, [Bulgarelli] 147—ab
  cancer, radical partial hepatectomy for, [Brunschwig] 1559—ab
  cirrhosis, diet in, (panel discussion) [Snell & others] *116
  cirrhosis, esophagoscopic and x-ray diagnosis of esophageal varices in, [Brick] 438—ab
  cirrhosis, management of bleeding esophageal varices in, [Hamilton] 1319—ab
  coma, [Andrews] 509—ab
  coma, physiopathology; glutamic acid for, [Cachera] 1217—ab
LIVER—Continued
  coma, symptoms; etiology; treatment, (panel discussion) [Snell & others] *116
  disease, anemia of, [Jandl] 594—ab
  disease (delayed) from fluoride dust? 623
  disease, panel on, [Snell & others] *116
  disease, significance of lowering serum vitamin E in, [Bäumer] 1313—ab
  disease, toxic hepatosis with intrahepatic obstructive jaundice after chlorpromazine, Atophan, arsphenamine and methyltestosterone, [Maier] 1326—ab
  disorders of parenchyma, thyroid function in, [Scazziga] 1397—ab
  disorders with cardiovascular disease, skin signs, [Silverman & Bernstein] *821
  function normal in pregnant women after cobalt supplements, [Holly] *1349; 1371—E
  hepatic catheterization and upper gastrointestinal hemorrhage in portal hypertension, [Browne & Welch] *106
  Hepatolenticular Degeneration: See Lenticular Nucleus
  in eclampsia, Brazil, 136
  Inflammation: See also Hepatitis, Infectious
  inflammation, sporadic acute anicteric hepatitis with respiratory infection, [Chancey & Zatz] *1013
  insufficiency, function tests to diagnose, (panel discussion) [Snell & others] *116
  posthepatitic syndrome, [Kallai] 1468—ab
  pulsating detected by recording from hepatic veins through brass cannula, [Sancetta] *922
  sclerosis, glycogenosis and; atypical Gierke's disease or secondary glycogenosis? [Bulgarelli] 147—ab
  surgery, hepatectomy, radical partial, for cancer, [Brunschwig] 1559—ab
LIVING
  standard rising, England, 769

- paralytic, cortisone for, France, 1459
- pathology, Viennese society discusses, *1187*
- prevalence, U. S., 413; 489; 575; 678; 758; *860; 959*; 1040; 1179; 1289; 1378; 1451; 1535
- prize, Lawrence Poole memorial at U. *of* Edinburgh, 421
- problem in U. S., [Bauer] *1407
- program in Israel, 1451
- research, India, 868
- risk to household contacts in nonepidemic years, [Siegel] 1227—ab
- *symposium:* pathogenesis, epidemiology, immunity, complications, Switzerland, 688
- *tonsillectomy* during season and during Salk vaccine? *1406*
- tonsillectomy relation to, Medical Research Council report, England, 1544
- *vaccination, Salk method* in Denmark, 213
- vaccine (Salk), allocations, 1462
- vaccine *(Salk), A.M.A.* resolution on commendation of Dr. Jonas Salk, 664; 745
- vaccine (Salk), considerations in preparation and use, [Salk] **1239*; 1282—E
- vaccine (Salk) *contraindicated* in *active* atopic dermatitis? 1406
- vaccine *(Salk) controversy, original* work by Dr. John A. Kolmer in *early 30's*, [*Ranieri*] 870—C
- vaccine (Salk), dissaprove *role of politics*, press and National Foundation for Infantile Paralysis in announcing results, [Brescia; Hoeppner] 585—C
- vaccine (Salk), *gamma globulin with affect* antibody response? 1483
- vaccine (Salk) in control of *poliomyelitis;* role of U. S. Public Health Service, [Scheele] *1271; 1282—E
- vaccine (Salk), 1954 field trial, (plan, field operations and follow-up) [Dublin] *1258; (effectiveness in preventing paralytic poliomyelitis) [Francis] *12[illegible] 1282—E
- vaccine (S[illegible] after, precipitated in carriers by negative *phase? 619*
- vaccine (Salk) production and studies in England under Medical Research Council, 966; (to be available this year) 1191
- vaccine (Salk) production, monkeys *available through USPHS, 1462*
- vaccine (Salk), public health implications; problems of licensing and standardizing vaccine, [Scheele & Shannon] *1249; 1282—E
- vaccine (Salk) purchase and distribution by U. S. government, (A.M.A. resolutions on) 664; 848; (statement of Dr. Price on proposed legislation S. 1984 and S. 2147) 834
- vaccine (Salk), safety of Cutter vaccine and time of administering during epidemic, [Hoeppner] 585—C
- *vaccine (Salk) sensitize to penicillin and streptomycin?* 1406
- vaccine (Salk), single-syringe-multiple-*needle* change cause homologous jaundice? 1406
- vaccine (Salk), statement of Dr. Walter B. *Martin*, 483
- *vaccine (Salk)*, status report by A.M.A. Board of Trustees, 308—E; 745
- vaccine (Salk), tonsillectomy and adenoidectomy advisable during? 619
- vaccine (Salk), will it sensitize Rh-negative *person to* Rh factor? 440
- vaccine (*trivalent-active*) developed by Prof. R. Haas, Germany, 138
- virus, accidental self-inoculation by laboratory technician, 583; [McMath] 880—ab
- virus and antibody, colorimetric test for, [Lipton] 518—ab
- virus, 2 types found in feces of healthy one-year-old in isolated community, England, 1047
- vital capacity to measure spontaneous breathing ability, [Ferris] 785—ab
- World Health Assembly (8th) discusses, 1197; [Diehl] 1198—C

POLITICS
- general election and medicine, *England*, 1544
- patients, *or* both; physicians *relations* to, England, 1457
- physician's *relation* to; warning of socialized medicine, President Hess' *page* discusses, 1528
- role in announcing Salk vaccine results, physicians dissaprove, [Brescia; Hoeppner] 585—C

POLYARTHRITIS: See Arthritis, Rheumatoid
POLYCYTHEMIA
- etiology in rats: cobaltous chloride, [Scott & Reilly] *1355; 1371—E
- hypernephroma and, [*Gros*] 1476—ab

POLYCYTHEMIA—Continued
  in ocular pathology, new theories of vascular disease, [Birge] 1142—ab
  treatment, radioactive phosphorus, [Harman] 889—ab
  with uterine myomas, [Horwitz & McKelway] *1360
POLYDIPSIA: See Thirst
POLYETHYLENE
  catheter (simple) for operative cholangiography, [Block & Orloff] *920
POLYGLOBULISM: See Polycythemia
POLYHYDRAMNIOS
  hydramnios (acute) with chorio-angioma, [McInroy] 604—ab
  hydramnios (maternal) and congenital central nervous system anomalies, [Prindle] 989—ab
POLYPS
  in bladder neck of female, transurethral resection for, 1000
  in colon and rectum, x-ray diagnosis, [Andrén] 1569—ab
POLYRADICULITIS: See Guillain-Barré Syndrome
POLYSACCHARIDES
  antituberculosis derivatives, [Barry] 790—ab
POLYVIDONE: See Povidone
POLYVINYL
  sponge (formalinized) to reinforce autogenous venografts to aorta in dogs, [Mortensen] 784—ab
  sponge (molded) to repair experimental interventricular septal defects during hypothermia, [Lewis] 1221——ab
  tube for suction and feeding in gastric surgery, [Trimble & Nouri] *1361
POLYVINYLPYRROLIDONE: See Povidone
POMEROY OPERATION
  for puerperal tubal sterilization, [Prystowsky & Eastman] *463
PONTOCAINE: See Tetracaine
POROKERATOSIS
  in man 55, Turkey, 774
PORPHYRIA
  herpes probably from, after sun exposure, (reply) [Greenberg] 624
PORTAL VEIN
  amebic liver infection in guinea-pigs via, [Maegraith] 86—ab
  catheterization and venography, [Bierman & others] *1331
  hypertension, Italy, 69; 686
  hypertension, catheterization and upper gastrointestinal hemorrhage in, [Browne & Welch] *106
  hypertension, shunt operation for bleeding esophageal varices, (panel discussion) [Snell & others] *116
  roentgen study, percutaneous splenoportography, [Figley] 351—ab; (spleen hemorrhage after) [Reynolds & others] *478
POSTGRADUATE Work: See Education, Medical
POSTMASTER
  General, physician as, England, 1047
POSTMATURITY
  fetal mortality and hypertension in mother, [Martin] 432—ab
POSTOPERATIVE: See Abdomen, surgery; Surgery
POSTURE
  hanging position for acute low back pain, [Kelly & Johnson] *1520
  scoliotic, in children, new therapy, [Baron] 1142—ab
POTASSIUM
  chloride in fluid and eletrolyte therapy in children, [Snyder] *1004
  cyanide to remove silver nitrate stains, (reply) [Andersson] 358
  depletion and replacement in hyperemesis gravidarum, [Fitzgerald] 989—ab
  depletion from aldosterone, 1444—E
  depletion not present in prednisone therapy, [Dordick & Gluck] *166; [Margolis & others] *454; [Robinson] *473; [Demartini & others] *1505
  in blood, hypopotassemia and alkolosis in anorexia mentalis, [Rossier] 1397—ab
  iodide dosage for asthma, [Unger] 505—C; (reply) [Engelsher] 1308—C
  metabolism, acute alkalosis relation to, [Kleeman] 1316—ab
  penicillin compared with benzathine and procaine penicillin, [Budolfsen] 1565—ab
  toxicity from massive doses of potassium penicillin, other possible diagnoses: tetany; water intoxication, [Keith] 424—C
POTT'S DISEASE
  lumbar, in adult, early diagnosis and treatment, [De Sèze] 1320—ab
  midlumbar, in adult, surgical treatment, [Debeyre] 1470—ab
POVIDONE (Kollidon; Periston-N; Polyvidone; Polyvinylpyrrolidone; Vinisil)
  treatment of tetanus, [Bickel] 517—ab
PRACTICE of Medicine: See Medicine, practice; Physicians, practicing
PRAYER
  physician's quoted from *South African Medical Journal* and*J.A.M.A.*, [Taylor] 690—C
PREDNISOLONE
  toxicity: side-effects, [Bollet & others] *459
PREDNISONE (Meticorten)
  toxicity: side-effects, [Bollett & others] *459
  treatment, cortisone compared, [Demartini & others] *1505
  treatment of allergies, [Arbesman] 1477—ab
  treatment of asthma, [Barach] 1396—ab
  treatment of rheumatic diseases, comparative studies, [Dordick & Gluck] *166; [Margolis & others] *454
  treatment of selected dermatoses, [Robinson] *473; (correction) 758
PREGNANCY
  advisable in healthy woman 43 with 2 normal children? 150
  advisable in woman with possible brucellosis 10 years previously? 93
  cobalt and iron effect on, [Holly] *1349; 1371—E
  complications: anemia; transfusion for? 1575
  complications: anxiety, [Reynolds] 84—ab
  complications: bicornate uterus, 892
  complications: diabetes and prediabetes, [Moreau] (fetal mortality and hypertrophy) 231—ab; (prevention and treatment of diabetic complications) [Moreau] 232—ab
  complications: gallstones, bile salts for; thyroid of no value, 150
  complications: heart disease, serial vital capacity determinations in, [Humphrey-Long] 788—ab
  complications: hydramnios, congenital central nervous system anomalies in infant, [Prindle] 989—ab
  complications: hypertension, survival of postmature fetus, [Martin] 432—ab
  complications: iron-deficiency anemia, [Gatenby] 989—ab
  complications: kala-azar, also in infant at 6 months, India, 868
  complications: leg cramps from excess calcium and phosphorus? 621
  complications: mitral stenosis, (commissurotomy for) [Glover & others] *895; (valvotomy at full term for, England) 1458
  complications: nasal congestion, 523
  complications: retinopathy, interrupt pregnancy for? [Heydenreich] 1140—ab
  complications: thrombocytopenic purpura, [Newmark] *646
  complications: tuberculous meningitis, [Marín Pittaluga] 432—ab
  complications: varicose veins, treatment, 1482
  diagnosis, accuracy of tests affected by hot weather, 519; (reply) [Berman] 1576
  duration, postmaturity and hypertension, [Martin] 432—ab
  duration prolonged, Austrian society discusses, 1456
  ectopic tubal, 37 cases, [Ouimet] 1560—ab
  incidence after puerperal tubal sterilization, [Prystowsky & Eastman] *463
  incidence after vaginal surgery, [Olki] 1473—ab
  role of internal secretion of placenta, Austria, 136
  toxemia, blood transfusion for, Austria, 1385
  toxemia, tracheotomy for, [Collins] 698—ab
  vomiting and nausea in, (chlorpromazine for) [Benaron] 788—ab (promethazine for) [Fitzgerald] 1560—ab
  vomiting in, potassium depletion and replacement in, [Fitzgerald] 989—ab

  - treatment, salicylates, effect on vitamin C stores, [Albanese] 779—ab

SODIUM—Continued
  cyanide to remove silver nitrate stains, (reply) [Andersson] 358
  excretion, renal blood flow, glomerular filtration rate, cardiac output and blood pressure relationships in heart disorders, [Werkö] 1467—ab
  hydroxide plus acetic acid in treating black tongue from penicillin troches, 91
  in coffee, tea, and cocoa, (Chemical Laboratory article) [Martinek & Wolman] *1030
  iodide effect on hyperthyroidism to show it is not hyperpituitarism, [Werner] 1550—ab
  low diet, difficulties and value of, [Allen] 689—C
  low diet, role of proteins in, Switzerland, 1197
  low diet, urine test to estimate degree of adherence to, 1238
  low sodium syndromes, [Margolin] 1313—ab
  nitrite poisoning from machine oil in girl 11, exchange transfusion for, [Kirby] 600—ab
  Pentothal: See Thiopental
  retention from skin absorption of fludrocortisone acetate, [Fitzpatrick & other] *1140
  retention not present in prednisone therapy, [Dordick & Gluck] *166; [Robinson] *473; (cortisone and prednisone effects compared) [Demartini & others] *1505
  thiosulfate to remove silver nitrate stains, (reply) [Blair] 358
SODOMY
  sperm recognition in anus 12 hours after assault, 441
SOLDIERS
  American, killed in Korea, coronary disease in, [Enos & others] *912
  causes of death in peacetime; high incidence of suicide, Denmark, 1300
SOLLMANN, TORALD, citation for by A.M.A., 749
SOMATOTROPIN (STH; somatotropic hormone)
  treatment of decubitus and neurotrophic disorders, [Ravina] 428—ab
SOUL, nutrition and hygiene of, mink coats and Cadillacs, [Newell] *381
SOUND
  barrier, breaking, effect on public, [Talbot] *1508
  basilar rales in myocardial infarction, [Kaufman & Caputo] *1521
SOUTH AMERICA
  health and sanitation program by Special Service of Public Health; joint U. S.-Brazil organization, 496
SOUTHEY TUBES
  in management of arm lymphedema, [Fox] 775—C
SPARGANOSIS
  second case in South America; [Osimani] 1220—ab
SPASM
  cortisone and hydrocortisone effect on hemiplegia after cerebral infarction, [Sheely & others] *803
  muscular, delayed pain of injection, [Travell] *368
  muscular, relieve for acute low back pain, [Kelly & Johnson] *1520
SPECIALISTS
  census of students in National Service Hospitals, England, 69
  consultation services, A.M.A. resolution on, 842
  medical education director, experiment: hospital as graduate medical center, [Jeghers & others] *245
  National Health Service needs, England, 1304
SPECIALTIES
  A.M.A. Special Committee on General Practice Prior to Specialization report, 750
  future of internal medicine, (Chairman's address) [Lewis] *1414
  importance of internship from standpoint of Specialty Board, [Boyd] *1156
  postgraduate and graduate courses for physicians according to, 1955-1956, 1033—E; *1052
SPEECH
  correction degree offered by West Virginia University, 1450
  disorders, pediatric, Wieboldt Foundation grant to Northwestern for study, 754
  remedial, workshop, S. D., 756
SPEED, KELLOGG (1879-1955)
  death of, (photo) 1183
SPEED
  responsible for automobile accidents, not lack of safety devices, [Wiedemann] 1199—C
SPERMATOZOA
  in anus, recognition 12 hours after assault, 441
ENARD
  of neurocirculatory asthemia,
  ito, to relieve pain of
  a cancer, 522
  tomyelia, [Holman] 84—
SPINAL CORD—Continued
  compression from spontaneous epidural hemorrhage, [Amyes] 602—ab
  roentgen study, myelography vs. discography to diagnose herniation or protrusion of intervertebral disk, [Wolkin] 1567—ab
SPINAL FLUID: See Cerebrospinal Fluid
SPINE
  ankylosing spondylitis with leukemia, England, 214
  ankylosing spondylitis, x-ray for; death rate from leukemia after, England, 1544
  degenerative disk disease, backache from, 998
  discography vs. myelography to diagnose herniation or protrusion of intervertebral disk, [Wolkin] 1567—ab
  fusions for tuberculosis, bone grafts in, [Eichenholtz] 984—ab
  intervertebral disk, neglect of lesions, England, 498
  lumbar, localized osteochondritis of, [Lamb] 85—ab
  rheumatoid spondylitis, cortisone for; severe adrenocortical insufficiency after joint manipulation, [Harnagel & Kramer] *1518
  scoliotic postures in children, new therapy, [Baron] 1142—ab
  tuberculosis, lumbar Pott's disease, diagnosis and treatment, [De Sèze] 1320—ab
  tuberculosis, midlumbar Pott's disease, surgical treatment, [Debeyre] 1470—ab
  tuberculous spondylitis mortality rate, Sweden, 584
SPIRAMYCIN
  treatment of infectious diseases, [Darbon] 1326—ab
SPLEEN
  antibody production in, in rabbit; cortisone, chemicals, body weight and spleen weight effect on, [Mountain] 1327—ab
  aspiration in clinical and experimental hematology, [Watson] 223—ab
  cancer metastases in from bronchus, uterine cervix, stomach and ovary, [Dunn] 700—ab
  dyssplenism secondary to chronic leukemia or malignant lymphoma, splenectomy for, [Reinhard & Loeb] *629
  extract in aortoiliac obliteration, [Martorell] 435—ab
  hemorrhage after percutaneous splenoportography, [Reynolds & others] *478
  hypersplenism, acquired agammaglobulinemia with, [Rohn] 595—ab
  infarction with hypoxia during high altitude flight, [Jernigan] 229—ab
  role in thrombocytopenic purpura in pregnancy, [Newmark] *646
  rupture, [Connell] 1471—ab
  rupture incidence in infectious mononucleosis, 802
  thorotrast, [Samuel] 1568—ab
SPLENOPORTOGRAPHY
  percutaneous, [Figley] 351—ab
  percutaneous, splenic hemorrhage after, [Reynolds & others] *478
SPONGE
  left in abdomen during cesarean section, England, 770
  polyvinyl formalinized, to reinforce autogenous venografts to aorta in dogs, [Mortensen] 784—ab
  polyvinyl molded, to repair experimental interventricular septal defects during hypothermia, [Lewis] 1221—ab
SPRUE
  syndrome, blood iron test to assess hematinics in, England, 770
SPUTUM
  for culture purposes, methods to obtain, 705
SPAGHETTI donor sets to prevent hemolysis in blood collected for plasma, [Murphy & others] *449
STANDARD Nomenclature of Diseases and Operations: See Terminology
STAPHYLOCOCCUS
  aureus, antibiotic resistance of 100 strains in plastic surgery unit, [Bramley] 1223—ab
  endocarditis, [Fisher] 222—ab
  enterotoxin produced by micrococci from enteritis after antibiotics, [Surgalla & Dack] *649
  infection in newborn, erythromycin for, [Forfar] 606—ab
  infections, antibiotic-resistant, guest editorial by Dr. Finland, 188—E
  pathogenic, in environment of the newborn, [Edmunds] 981—ab
STARCH
  effect on celiac disease, [Hansted] 1142—ab
  oxidized, antituberculosis agents from, [Barry] 790—ab
STARVATION
  cytochrome C in inanition of rabbits, Switzerland, 1197
  infection resistance lowered in mice by, England, 1190
STATE
  voluntary services and, saved 2 cases of tuberculosis of lungs, England, 1458
STATE BOARD
  future of internship from standpoint of, [Ezell] *1161
STATE BOARD—Continued
  Medical Licensure Statistics for 1954, May 28, *269; 308—E
  Washington state's basic science law, [Dohm] 1050—C
STEEL
  stainless, plus vitallium metal in plating of fractures, adverse reactions from? 93
  sutures for correcting inguinal hernia? 1145
STERILITY, BACTERIAL
  air conditioning effect on operating room contamination, [Edwards] 598—ab
  of surgical packs, 241
STERILITY, SEXUAL
  endocervical forceps to evaluate cervical factor in, [Palmer] *1281
  latent genital tuberculosis in women as cause of, [Halbrecht] 1473—ab
  niddah (postmenstrual abstention from coitus) cause of, England, 1192
  treatment, cortisone, Austrian society discusses, 1456
  treatment, diet high in vitamins and proteins, 620
STERILIZATION, BACTERIAL
  of syringes and needles with commercially softened water hazardous? 894
  radioactive, of food, England, 1047
STERILIZATION, SEXUAL
  medicolegal curriculum advocated, [Hall] *257
  plus cortisone for breast cancer, [Meyer] 599—ab
  puerperal tubal, [Prystowsky & Eastman] *463
STERNUM
  puncture (extended suprasternal) to study blood flow on left side of heart, [Radner] 779—ab
STEROID
  anesthesia in surgery, [Murphy & others] *1412
STILBAMIDINE
  treatment of blastomycosis, [Smith & others] *641
  treatment of tic douloureux, [Smith] 989—ab
STOMACH
  anesthesia for trauma when full, 520
  cancer and sarcoma, [Walters] 1471—ab
  cancer, biological behavior especially survival rates, [Macdonald] 697—ab
  cancer differentiated from ulcer, (Chilean society discusses) 767; (by x-ray) [Kirsch] 793—ab
  cancer, familial study, [Hagy] 145—ab
  cancer, metastases in spleen, [Dunn] 700—ab
  cancer of antrum, radical subtotal gastric resection for, [Mayo] 1558—ab
  cancer possible from swallowing detached cells from tongue cancer? 522
  cancer, surgical treatment, total gastrectomy, [Chieppa] 229—ab
  crisis of tabes dorsalis, chlorpromazine for, France, 1459
  gastroduodenal hemorrhage, Peru, 687
  inflammation, atrophic gastritis of fundus in pernicious anemia: biopsy, [Debray] 1401—ab
  lavage and vitamin K_1 in Warfarin poisoning, 93
  mucosa in patients with pulmonary tuberculosis, [Vague] 80—ab
  mucosa prolapse (transpyloric), subtotal gastrectomy for, [Hermann & others] *1169
  mucosa, vitamin B_{12} effect on in pernicious anemia, [Celli] 1218—ab
  oxygen (intragastric) for ascariasis, India, 686
  secretion (basal), anticholinergic drugs effect on, [Sun & others] *713
  secretion, histamine in activating, British Societies discuss, 769
  secretion in activation of peptic ulcers by corticotropin, [Hirschowitz & others] *27
  Surgery: See also Peptic Ulcer, surgical treatment; Stomach cancer
  surgery, gastrectomy, morbidity and mortality, Peru, 330
  surgery, gastrectomy, peritoneum closure after, 521
  surgery, gastrectomy, psychotherapy after, Peru, 688
  surgery, gastrectomy (subtotal) for transpyloric mucosal prolapse, [Hermann & others] *1169
  surgery, gastrectomy (total), problem of nutrition after, [Johnson] 1225—ab
  surgery, gastrojejunostomy, irritation from, with glaucoma and mucous colitis, therapy, 241
  surgery, resection and gastrectomy, kathepsin and pepsin after, [Pfisterer] 341—ab
  surgery, resection, Italian convention discusses, 1305
  surgery, resection; melena from persistent suture in, [Schrijver] 987—ab
  surgery, resection (subtotal), with colon substitution, [Watkins] 1559—ab
  surgery, technique combining suction and feeding after, [Trimble & Nouri] *1361
  tuberculous ulcer, India, 1048
  Ulcer: See Peptic Ulcer

STOMACH TUBE
  conjunctival petechiae after use of, [Majoros] 505—C
STOMATITIS
  aphthous, iritis with, does this represent Behcet's syndrome? 91
  aphthous, monoxychlorosene for, [Zwerling] 1330
  aphthous, Pan American conference discusses, 766
STOVE
  hot, cause of burns in children, [Bleck] *100
STRAIN
  rectosigmoid colon perforation from, [Birbis] 1320—ab
STRANDQVIST CURVE
  correlating field size and x-ray dose for skin cancer, [Allen & Freed] 157:1272, April 9, 1955; (correction) 158:61, May 7, 1955
STREPTOCOCCUS
  bacteriological procedures to diagnose? 522
  detection: human vs. sheep blood agar in acute tonsillitis and pharyngitis, [Nuessle] 613—ab
  group A in rheumatic fever, monthly benzathine penicillin G injection to prevent, [Stollerman] 1322—ab
  group A infection and sequelae, sulfadiazine or penicillin to control, [Wannamaker] 1323—ab
  infection, benzathine penicillin G to prevent, [Esbenshade] 1229—ab; [Tidwell] 1323—ab
  infections (beta hemolytic) in children, single benzathine penicillin G injection for, [Breese] 1230—ab
  sore throat problem in U. S., [Bauer] *1407
STREPTOMYCIN
  Dihydro—: See Dihydrostreptomycin
  effect plus isoniazid on acid-fastness, tetrazolium reduction, growth and survival of tubercle bacilli, [Koch-Weser] 780—ab
  in fluid for shipping blood specimens, [Cahan] 971—C
  penicillin combination, in vitro studies, [Kylin] 1566—ab
  Salk vaccine sensitized to? 1406
  treatment alone and with PAS and isoniazid in genitourinary tuberculosis, [Dean] 609—ab
  treatment of tuberculosis, England, 213
  treatment of tuberculous meningitis, [Klebanov] 232—ab; (Finland) 421: (optic nerve lesions increase during) [Janssen] 1325—ab
  treatment plus chemotherapy in tuberculosis, Austria, 764
  treatment plus cortisone in pulmonary sarcoidosis, [Hoyle] 780—ab
  treatment plus isoniazid in exacerbation of tuberculosis 20 years later; how long? 1237
  treatment plus isoniazid in ulceronodular tuberculosis, [Véran] 596—ab
  treatment plus isoniazid or PAS in tuberculosis, (Council article) [King] *829
  treatment plus PAS and early aspiration in tuberculous pleural effusions, [Emerson] 341—ab
  treatment plus PAS in tuberculosis, Turkey, 773
  treatment plus PAS (prolonged) in tuberculosis, relapse after lung resection during, [Capel] 1318—ab
  treatment plus Pasdrazide in renal tuberculosis, [Aveta] 1475—ab
  treatment plus tetracycline for chronic brucellosis, 705; (reply), [Harris] 1484
  tubercle bacilli resistant to, Finland, 421
STREPTOPAS
  treatment of leprosy, India, 1048
STREPTOTRICHOSIS: See Nocardiosis
STRESS
  cold, pituitary and thyroid role in phosphorus metabolism of adrenals during, [Nicholls] 1402—ab
  in coronary disease pathogenesis in American soldiers killed in Korea, [Enos & others] *912
  incontinence, [Elgosin] 689—C
  infection resistance lowered in mice by, England, 1190
"STROKES": See Brain hemorrhage
STUDENTS
  psychiatric treatment of at Cornell University, N. Y., 1533
STUDENTS, MEDICAL
  A.M.A. resolutions on draft of, 936
  A.M.A. resolutions on endorsing Student Aid Bill H. R. 4444, 848
  educational trust fund by El Paso County Medical Society, 1178
  International Federation of Medical Students Association confused with communistic International Union of Students, 657—E
  Student American Medical Association Foundation to be established to provide loans, 668
  Student A.M.A., introduction and remarks of delegates, 668
  tuberculosis in, U. of Minnesota survey, [Myers & others] *1
SUBARACHNOID HEMORRHAGE: See Meninges
SUBDURAL: See Meninges
SUBSTANCE VI: See p-Methylbenzenesulfonamide
SUBURBS: See Cities and Towns
SUCCINYLCHOLINE
  safe as muscle relaxant adjunct to general anesthesia, 523; 621
SUCTION
  feeding and, after gastric surgery, technique combining, [Trimble & Nouri] *1361
SUDECK'S SYNDROME
  after fractures, [Bierling] 350—ab; (metatarsal fracture) 703
  treatment, ganglion blocking, [Götze] 157: 1444—ab, April 16, 1955.
  treatment, vitamins D and E, [Beckmann] 145—ab
SUGAR
  dental caries not significantly affected by, Medical Research Council report, England, 1045
  invert, in fluid and electrolyte therapy in children, [Snyder] *1004
SUICIDE
  attempts, barbiturate, Sweden, 422
  common cause of death, Sweden, 422
  incidence high in soldiers in peacetime, Denmark, 1300
  prevention, role of psychoses in attempts, Austria, 1385
  with chlordane, (Council article) [Derbes & others] *1367
SULFADIAZINE
  to control group A streptococcal infections and sequelae, [Wannamaker] 1323—ab
SULFONAMIDES
  micrococcic infections resistant to, guest editorial by Dr. Finland, 188—E
  presulfonamide, pencillin and, otitis media during eras, [Davison] 884—ab
  treatment of bacillary dysentery in World War II reduced mortality, Austria, 764
  treatment of bacterial complications of colds in children, 92
  treatment plus penicillin in surgical infections, [Rubino] 1327—ab
SULFURIC ACID
  fumes, hazard of, 240
SUMP PHENOMENON
  for resistant edema, [Schemm] 597—ab
SUNLIGHT: See Light
SUPRARENALS: See Adrenals
SURGEONS
  anesthetic team; sucking out trachea with catheter, [Koontz] 1050—C
  Royal College of Surgeons' 450th anniversary, 1388
  Ten Commandments of, by Dr. Alfonso Bonilla Naar, [Gomez] 775—C
SURGERY
  British Medical Association leaflet on bequeathing human body for, 499
  extracellular fluid response to, [Kovach] 230—ab
  Fulbright lecturers needed in Italy, 1534
  Harvard surgical unit, new, 1375
  how to make it pay, reprinted from *Punch* [Gordon] *591
  hypotension induced during, [Little] 1402—ab
  International College of Surgeons Woman's Auxiliary awards, 205
  lamp (Schreiber neurosurgical) for, [Bolman & Lloyd] 423—C
  ligature carrier for blood vessel surgery, [Lyall] 690—C
  new journal: *Journal of Surgery, Gynecology and Obstetrics*, Philippines, 584
  new journal: *Survey of Surgical Techniques*, 859
  nutrition in surgical patients, (Council article) [Crandon] *264
  operating room, air conditioner designed for explosive atmospheres, 1405
  operating room air contamination, air conditioning effect on, [Edwards] 598—ab
  plastic, digital flexor tendon grafts, [Boyes] 1472—ab
  plastic, first International Congress of Plastic Surgery to convene in Sweden, Aug. 1-5, 1180
  plastic, free nail grafting, [McCash] 1223—ab
  plastic, of head and neck, graduate course, Chicago, 1286
  plastic, to reconstruct hand digits by toe transfers [Clarkson] 986—ab
  plastic unit, antibiotic resistance of Staphylococcus aureus in [Bramley] 1223—ab
  postoperative recurrence of colon cancer from desquamated malignant cells, [Pomeranz & Garlock] *1434
  postoperative ventral hernia, tantalum mesh wire to reenforce suture for, [Floyd] 1319—ab
  postoperative vomiting, Marezine for, [Marcus] 1472—ab
  preoperative and postoperative use of parenteral vitamin B complex and intravenous vitamin C, waste by urinary excretion? 440
SURGERY—Continued
  preoperative skin preparation, zephiran vs. merthiolate; also tincture of iodine and hexachlorophene soap, 619
  risk in cardiovascular patient, Peru, 1196
  surgeon takes second look at: relation to medicine as whole, [Ravdin] *532
  tissue bank and military medicine, [Coyl & Kindred] *171
  traumatic, and orthopedics, Peru, 687
  vs. x-ray for pituitary adenomas, [Horrax] 700—ab
SUTURES
  cardiovascular needle holder, [Giannini] *1441
  epithelial stitch for cutaneous wounds, [Pecora] 776—C
  ligature carrier (modified) for blood vessel surgery, [Lyall] 690—C
  persistent, in resected stomach, melena from, [Schrijver] 987—ab
  steel to correct inguinal hernia? 1145
SWALLOWING
  dysphagia with aortic sclerosis, [Keates] 872—ab
SWEAT GLANDS
  absence of, ectodermal dysplasia presenting as fever, [Stiles & Weir] *1432
SWEDISH
  Church Mission, medical activities in Africa, 70
SWISS
  Society of Internal Medicine, annual meeting, 1306
SYMPATHECTOMY
  endarteriectomy and, for arterial stenosis leading to gangrene, [de Takats] *1502
  extended in arterial hypertension, (immediate results) [Martin] (late results) [Joly] 1318—ab
  lumbar, for peripheral vascular disease, 523
  pericarotid, for chronic polyarticular rheumatism, Turkey, 773
  treatment effective in hypertension if drugs fail? 706
SYMPATHICOGONIOMA (neuroblastoma) [Uhlmann] 881—ab
SYMPATHOLYTIC DRUGS
  dihydroergotamine effect on intact uterus, [Garrett] 1140—ab
SYMPTOMS
  subjective, drugs to alter appraised, (Council article) [Beecher] *399
SYNOVIAL FLUID
  changes in rheumatoid arthritis, [Robinson] 510—ab
SYPHILIS
  congenital (early), penicillin for, [Smith] 607—ab
  congenital, interstitial keratitis complicating, cortisone for, [Horne] 993—ab
  early, penicillin G with aluminum monostearate for gonorrhea without masking, 357
  in industry; mass blood testing; employment policy regarding syphilitics, [Downing] *469
  serodiagnosis, manual of tests, USPHS 1955 edition, 1462
  serodiagnosis of familial type: treponema immobilization test, [Tramier] 978—ab
  serodiagnosis, positive tests without signs of disease, treatment, 1235
  serodiagnosis, unsuspected positive tests, Sweden, 1546
  serodiagnosis, what percentage of general paresis or taboparesis patients show negative tests? 1484
SYPHILOLOGY

THYROID
  cancer, Brazil, 1298
  cancer and nodular goiter, [Todd] 983—ab
  cancer in children, [Weinbren] 84—ab; [Buckwalter] 511—ab
  cancer in nodular thyroid, thyroidectomy for, (Diagnostic Problems) [Thorpe] *1362; (comment) [Eckert] *1363
  cancer, metastatic, after nailing femur fracture; thyroidectomy and radioactive iodine for, Austria, 1542
  cancer, symposium, Peru, 330
  diseases, TSH to diagnose, [Bishopric] 593—ab
  dysfunction, cobalt in etiology, [Keitel] 1390—C
  euthyroid patients with early eye signs of Graves' disease, L-triiodothyronine and thyrotropin for, [Werner] 1313—ab
  extract plus cortisone for endocrine deficiencies following hypophysectomy, Switzerland, 1306
  extract, rationale in mental disorders, 1483
  function, cobalt effect in mice, [Holly] *1349; (in rats) [Scott & Reilly] *1355; 1371—E
  function in children receiving cobalt, [Jaimet & Thode] *1353; 1371—E
  function in hepatic parenchyma disorders, [Scazziga] 1397—ab
  hormone to differentiate hyperthyroidism and euthyroidism, [Perlmutter & Slater] *718
  hyperplasia in young children, role of cobalt and iron in, [Klinck] *1347; 1371—E
  insufficiency (acquired) in adults, hypertrophic muscular dystrophy with, [Picard] 1215—ab
  lingual, in siblings, I^{131} to diagnose and treat, [Springer] 884—ab
  preparations in surgical management of pituitary chromophobe tumor, [Gurdjian & others] *23
  preparations of no value for gallstones in pregnancy, 150
  preparations plus thiourea for endocrine exophthalmos, [Del Maschio] 342—ab
  role in phosphorus metabolism of adrenals during cold stress, [Nicholls] 1402—ab
  tumors, Hürthle-cell, [Gardner] 614—ab
THYROIDECTOMY
  analysis of 12,000 operations, Austria, 327
  vocal cord paralysis with hypothyroidism and hypoparathyroidism after, [Ranke & Holinger] *543
THYROIDITIS
  granulomatous, with anisotropic crystalline material, [Gross] 888—ab
THYROTOXICOSIS: See Goiter, Toxic
THYROTROPIN (TSH; Thyrotropic Hormone)
  thyroid disease diagnosed by, [Bishopric] 593—ab
  treatment of euthyroid patients with early eye signs of Graves' disease, [Werner] 1313—ab
THYROXIN
  infection resistance lowered in mice by, *England, 1190*
  therapy in preventive geriatrics, [Starr] 982—ab
TIC Douloureux: See Neuralgia, trigeminal
TICKS
  infestation, preventing with N-butylacetanilide, 242
TINEA
  capitis and corporis from dog and cat, 1330
  capitis from M. audouini and M. canis; host-parasite relationship, [Kligman] 233—ab
TINNITUS
  aurium, any treatment effective? (replies) [Herzon; Miller] 358
  aurium, clicking in ear 10 years after fenestration, 1230
  aurium in both ears after flight, 998
TINTEX
  aniline dyes in cause acute hemolytic anemia? 801
TISSUES
  bank and military medicine, [Coyl & Kindred] *171
  cells, antihuman globulin deviation method to demonstrate fixed antibodies in, Austria, 1043
  connective, functions in carbon dioxide, ion and water exchanges and in enzyme functions and infection defense, Austria, 1385
  culture diagnosis of poliomyelitis and aseptic meningitis, [Godenne & Riordan] *707
  culture test for safety of Salk vaccine, [Scheele & Shannon] *1249; 1282—E
  regeneration, scar tissue impedes, France, 1048
  soft, hydrocortisone for lesions of, [Crisp] 595—ab
TOBACCO
  carbon monoxide from smoke causes death of birds, [Binet] 613—ab
  cigarette lighter fluid, poisoning in children from, [Thompson] 1231—ab
  cigarette smoking role in lung cancer etiology, (Peru) 330; (fear of in physicians, England) 1545
  industry research fellowships, 574
  infertility in tense, heavy-smoking man of 30, 620
  smoking and chewing in relation to upper alimentary tract cancer, [Sanghvi] 1215—ab
  smoking effect on cardiovascular system of normal and hypertensive people, [Roth] 340—ab
  smoking habits of physicians compared, [Snegireff] 977—ab
TOES
  hand digits reconstructed by toe transfers, [Clarkson] 986—ab
TONGUE
  black from penicillin troches; sodium hydroxide and acetic acid for, 91
  cancer, detached cells cause stomach cancer? 522
  inflammation, median rhomboidal glossitis, India, 1193
  tumors, fibroma of frenum linguae, chloramphenicol for, India, 1193
TONSILLECTOMY: See also Medicolegal Abstracts at end of letter M
  adenoidectomy and, advised for children taking Salk vaccine? 619
  blood coagulation tests before, status of, especially capillary tube test, 1574
  cyanosis during ether anesthesia after ethyl chloride; antibiotics pre- or postoperatively? 522
  during poliomyelitis season and during Salk vaccination? 1406
  poliomyelitis relation to, Medical Research Council report, England, 1544
TONSILS
  enlarged, relation to deafness, (replies) [Levy; Crowe] 442
  hemorrhage from, Austria, 1385
  human and sheep blood agar to detect streptococcus in acute tonsillitis, [Nuessle] 613—ab
  tonsillogenic sepsis; fever, myocarditis, hepatomegaly and splenomegaly disappear after tonsillectomy, Austria, 964
TOOTHPASTES: See Dentifrices
TOURNIQUET
  regulation of blood collection to prevent hemolysis, [Murphy & others] *449
TOXOPLASMOSIS
  acquired from laboratory infection, [Beverly] 510—ab
  acquired, in Britain, 137
  active connatal, in newborn infant, [Ariztia] 882—ab
  serodiagnosis, clinical significance of reactions, [Lelong] 144—ab
  toxoplasma antigen, new, Austria, 212
TRACHEA
  intratracheal goiter, Viennese society discusses, 1188
  sucking out with catheter: surgeon and anesthetist, [Koontz] 1050—C
  tumors, granuloma after anesthetic intratracheally, 1484
TRACHEOBRONCHITIS
  chronic ulcerative, antibiotic-resistant, definite diagnosis needed to establish treatment, 999
TRACHEOTOMY
  for vocal cord paralysis after thyroidectomy, [Ranke & Holinger] *543
  in severe preeclampsia and eclampsia, [Collins] 698—ab
  tube in situ, 2% sodium bicarbonate for mucus plugs? 1482
  tubes, care of with methyl cellulose preparations? 1483
TRACHOMA
  research program by Arabian American Oil Co. at Harvard, 570
  treatment, erythromycin, [Button] 790—ab
TRACTION
  head, for chronic hemicrania of unknown origin? 619
